**The Population, Agriculture and Environment Nexus
in Sub-Saharan Africa**

Kevin M. Cleaver and Götz A. Schreiber

**WORLD BANK
AFRICA REGION**

Over the past 30 years, most of Sub-Saharan Africa has seen very rapid population growth, poor agricultural performance, and increasing environmental degradation. Why do these problems seem so intractable? Are they connected? Do they reinforce each other? If so, what are the critical links? These are questions that this study seeks to answer. The approach was to review the literature and available country data to test the hypothesis that there are strong inter-relationships between these phenomena. The findings suggest that this nexus is very much at work in Sub-Saharan Africa and that development efforts would be far more effective if their design reflected this.

Key links are found in traditional crop and livestock production methods, land tenure systems, women's responsibilities, and methods of forest resource utilization. The traditional systems and practices were well suited to people's survival needs when population densities were low. As populations grew slowly, they evolved in response. But with the acceleration of population growth in the 1950s, these traditional ways came under increasing strain -- eventually to the point of being overwhelmed. The results have been the triad of problems noted at the outset.

The solutions to these problems are complex, which is why effective responses have not been forthcoming on a wide scale. The study suggests an action plan involving agricultural intensification, measures to increase demand by Africans for smaller families, land tenure reform, conservation efforts to address environmental problems, and actions to deal with the special problems of women. Important themes include the necessity for Africans themselves to lead this process. There is also an important need for incentives to create demand for agricultural intensification, for smaller families, and for conservation. The importance of relying on inter-relationships between these various parts of the solution in arriving at a significant impact on the problem is emphasized; hence the idea of a nexus of problems, and of solutions.

Several country-specific population, agriculture and environment nexus studies have been initiated to deepen this work, including in Côte d'Ivoire, Malawi, Nigeria, Rwanda and the Sahel as a sub-region. In addition data collection and statistical analysis of the hypotheses and findings described in this book are ongoing. This material will be added to the present text for formal publication as a World Bank document later in 1992.

UNEP	-	United Nations Environment Programme
WFS	-	World Fertility Survey

Acknowledgments

This study benefitted from considerable input by various staff members of the World Bank and people outside the Bank. S. Yalamanchili, Sandy Gain and Pushpa Schwartz contributed statistical material. An initial report setting out the hypotheses to be studied was the subject of a seminar held at the World Bank in June 1990, chaired by Michel Petit. Subsequently, seminars were held with the Country Departments of the Africa Region of the World Bank. Drafts of the study have been presented to representatives of African governments and donor agencies as well as non-governmental organizations at the West and Central African Rain Forest Conservation Conference in Abidjan in October 1990, academic fora organized by Monclair College in New Jersey in November 1990 and by the Harvard Center for Population and Development Studies in March 1992, an international conference on population issues in Africa organized by the Government of France in September 1991, staff of USAID in July 1990 and January 1992, and officials of the French Caisse Centrale de Cooperation Economique in Paris in January 1992. Members of the World Bank Africa Region's Thematic Team on the Population, Agriculture and Environment Nexus have also provided comments and input. These various inputs, and additional research stimulated by the comments and suggestions received, have resulted in this revised draft. A formal review in the World Bank of the final draft in December 1991 was chaired by Michel Petit.

Special thanks for support, comments, suggestions and contributions are due to: Kim Jaycox, Robert McNamara, Michel Petit, Steve O'Brien, Ismail Serageldin, Caio Koch-Weser, Anand Seth, Ishrat Z. Husain, Michael Gillette, Pierre Landell-Mills, Fred Sai, Dunstan Wai, Ishrat Husain, John Peberdy, Dennis Mahar, Leif Christoffersen, François Falloux, John English, Susan Cochrane, Althea Hill, Harry Walters, Agi Kiss, François Weneélius, Joanne Salop, Jean Doyen, Cynthia Cook, Willem Floor, Mary Dyson, Elizabeth Morris-Hughes, Julia Clones, Paul Shaw, John Spears, Moutar Touré, Phillippe Caquard, Montague Yudelman, Allen Kelley, Michael Paolisso, and staff of the FAO and the French Caisse Centrale. Finally, the comments and suggestions of three anonymous reviewers have been most useful and are acknowledged with particular gratitude.

THE POPULATION, AGRICULTURE AND ENVIRONMENT NEXUS IN SUB-SAHARAN AFRICA

Executive Summary

A. The Three Basic Concerns

i. **Population Growth.** Sub-Saharan Africa (SSA) lags behind other regions in its demographic transition. The total fertility rate (TFR) for SSA as a whole has remained at about 6.5 for the past 25 years, while it has declined to about 4 in all developing countries taken together.¹ As life expectancy in Sub-Saharan Africa has risen from an average of 43 years in 1965 to 51 years at present, population growth has accelerated from an average of 2.7 percent per annum for 1965-1980 to about 3.1 percent per year at present. Recent surveys appear to signal, however, that several countries -- notably Botswana, Zimbabwe, Kenya -- are at or near a critical demographic turning point.

ii. **Agricultural Performance.** Agricultural production in Sub-Saharan Africa increased at about 2.0 percent per annum between 1965 and 1980 and at about 2.1 percent annually during the 1980s. Average per capita food production has declined in many countries, per capita calorie consumption has stagnated at very low levels, and roughly 100 million people in Sub-Saharan Africa are food insecure. Food imports increased by about 185 percent between 1974 and 1990, food aid by 295 percent. But the food gap (requirements minus production) -- filled by food imports, or by many people going with less than what they need -- is widening. The average African consumes only about 87 percent of the calories needed for a healthy and productive life.

iii. **Environmental Degradation.** Sub-Saharan Africa's forest cover, estimated at about 679 million hectares in 1980, has been diminishing at a rate of about 3.7 million ha per annum, and the rate of deforestation has been increasing. As much as half of SSA's farm land is affected by soil degradation and erosion, and up to 80 percent of its pasture and range areas show signs of degradation. Degraded soils lose their fertility and water absorption and retention capacity, with adverse effects on vegetative growth. Deforestation has significant negative effects on local and regional rainfall and hydrological systems. The widespread destruction of vegetative cover has been a significant factor in prolonging the period of below long-term average rainfall in the Sahel in the 1970s and 1980s. It also is a major cause of the rapid increase in the accumulation of carbon dioxide (CO₂) and nitrous oxide (N₂O), two greenhouse gases, in the atmosphere. Massive biomass burning in Sub-Saharan Africa (savanna burning and slash-and-burn farming) contributes vast quantities of CO₂ and other trace gases to the global atmosphere. Acid deposition is higher in the Congo Basin and in Côte d'Ivoire than in the Amazon or in the eastern United States and is largely caused by direct emissions from biomass burning and by subsequent photochemical reactions in the resulting smoke and gas plumes. Tropical forests are considerably more sensitive than temperate forests to foliar damage from acid rain. Soil fertility is reduced through progressive acidification. Acid deposition also poses a serious risk to amphibians and insects that have aquatic life cycle stages; this risk extends further to plants that depend on such insects for pollination.

¹ The total fertility rate (TFR) is the total number of children the average woman has in a lifetime.

B. The Nexus in Brief

iv. Sub-Saharan Africa's demographic, agricultural and environmental problems are closely linked in a nexus of multiple and mutually reinforcing causality chains. Key linkages are found in traditional crop production and livestock husbandry methods, traditional land tenure systems and land use practices, traditional responsibilities of women in rural production and household maintenance systems, and traditional methods of utilizing woodland and forest resources. These systems and practices, well suited to people's survival needs on Africa's fragile resource endowment when population densities were low and populations stable or growing only slowly, came under increasing strain with the rapid acceleration of population growth that began when mortality rates declined sharply in the 1950s while birth rates remained high. The pace of evolution of these systems has been inadequate in the face of dramatically intensifying pressure of more people on finite stocks of natural resources.

v. Traditional land use and forest exploitation practices have become major direct causes of environmental degradation and resource depletion. This degradation reduces the productivity and resilience of natural resource systems. Despite considerable investment in yield-increasing technology, crop yields, especially of food crops, have stagnated or declined in many countries, retarding agricultural growth. Slow agricultural growth, contributing to slow aggregate economic growth, impedes the onset of the demographic transition from high to low birth rates. Rapidly growing poor rural populations increasingly degrade and mine the natural resources of the rural environment to ensure their own day-to-day survival. And continuing rapid population growth ties up scarce resources to meet current survival and consumption needs which could otherwise be used to create the base for less resource-intensive and more sustainable development.

vi. Many other factors also have a detrimental impact on agriculture and the environment. These include civil wars, poor rural infrastructure, lack of private investment in agricultural marketing and processing, and ineffective agricultural support services. Inappropriate price, exchange rate and fiscal policies pursued by many governments have reduced the profitability and increased the risk of market-oriented agriculture, prevented significant gains in agricultural productivity and contributed to the persistence of rural poverty. A necessary condition for overcoming the problems of agricultural stagnation and environmental degradation will be, therefore, appropriate policy improvements along the lines suggested in the 1989 World Bank report on Sub-Saharan Africa's longer-term development prospects (World Bank, 1989d).

C. Key Elements of the Nexus

vii. *Shifting Cultivation and Transhumant Pastoralism.* Shifting or long-fallow cultivation and transhumant pastoralism have been appropriate under conditions of slow population growth, abundant land, limited capital and limited technical know-how. The ecological and economic systems were in equilibrium. The key to maintaining this equilibrium was mobility. People shifted to a different location when soil fertility declined or forage was depleted. This allowed the fertility of the land to be reconstituted through natural vegetative growth and decay. For field cropping, this typically involved farming a piece of land for two to four years, then leaving it fallow for as long as 15 to 25 years. Herders' mobility generally involved a far greater geographic range, but a far shorter temporal cycle, dictated by the seasonal availability of water and forage.

viii. As long as land was abundant, more land could be gradually brought into the farming cycle to accommodate the slowly growing populations. Where population density increased slowly, the traditional extensive agricultural production systems gradually evolved into more intensive, and

eventually permanent, systems which included soil conservation, fertility management, various forms of agro-forestry and the integration of livestock into farming systems. This has happened, for instance, in the Eastern African highlands as well as in some of the more densely settled areas of northern Nigeria.

ix. But in most of Sub-Saharan Africa the scope for further expansion of crop land has drastically narrowed. Large areas of forests, wetlands, river valley bottoms and grassland savanna have already been converted to farmland. On average, per capita arable land actually cultivated declined from 0.5 ha per person in 1965 to 0.3 ha/person in 1987 (it averaged 0.4 ha/person in China in 1987). In many areas, rural people are increasingly compelled to remain on the same parcel of land, yet they continue to use their traditional production techniques. Soil fertility and structure deteriorate rapidly where fallow periods are too short and traditional cultivation methods continue to be used. As a result, crop yields decline and soils erode. In most areas, population growth has been so rapid that the reduction of arable land per farmer and the associated soil degradation have greatly outpaced the countervailing innovation and adjustment by farmers. When farming is no longer viable, people migrate to establish new farms on land previously not used for farming -- in semi-arid areas and in tropical forests where soil and climatic conditions are poorly suited to annual cropping. Migrants bring with them the knowledge of only those farming techniques they practiced in the areas they abandoned, and these are often detrimental to their new environment.

x. There is considerable diversity among countries, and in some countries land still appears to be more abundant in relation to their current population. But much of this land is under tropical forests which need to be preserved. Yet even in these more land-abundant countries, rapid population growth is pushing settlers to extend farming and grazing into areas that are agro-ecologically unsuited to these forms of land use.

xi. One of the conditions which stimulated Asian farmers to adopt "green revolution" technology -- the abundance of labor relative to cultivable land -- is increasingly emerging in parts of SSA. But institutions and individuals have not been able to adapt rapidly enough in the face of very rapid population growth. Slow technological innovation because of ineffective agricultural research and extension systems is only part of the reason. The poor transport infrastructure throughout most of SSA severely blunts farmers' incentives to switch from subsistence to market production and from extensive to intensive farming. Inappropriate agricultural marketing and pricing as well as fiscal and exchange rate policies have reduced the profitability of market-oriented agriculture, prevented significant gains in agricultural productivity and contributed to the persistence of rural poverty. Many poorly conceived and implemented agricultural projects have not helped.

xii. *Women's Time, and Their Role in Rural Production and Household Maintenance Systems.* In addition to those associated with bearing and rearing children, African women bear heavy responsibilities for foodcrop production, weeding and harvesting on men's fields, post-harvest processing, fuelwood and water provision, and household maintenance. In traditional settings this worked well, as both genders had clearly defined and complementary roles to ensure the present and future welfare of family, village, clan and/or tribe. But the burdens on rural women are increasing, as population growth outpaces the evolution of agricultural technology and growing numbers of men leave the farms for urban and industrial jobs. As forests and woodlands are cleared or severely degraded, it takes more time and effort to collect fuelwood. Deforestation and soil structure deterioration, combined with declining rainfall, reduce groundwater recharge and make water scarcer. Women must walk further to fetch water and fuelwood -- and get their daughters to help them. In most of rural SSA, women also are the primary "beasts of burden," spending substantial time headloading not only water and fuelwood, but also farm produce and other commodities to and from

their homes. Producing the needed food on increasingly less fertile plots and with diminished time becomes more difficult. Women also face severe restrictions on access to extension advice, institutional credit, and improved production, processing and transport technology. These constraints, combined with increasing pressure on women's time, severely impede productivity improvements and the intensification of women's farming operations.

xiii. Many factors underlie the persistence of very high human fertility rates. The fundamental problem is low demand for fewer children. Environmental degradation, agricultural problems, food insecurity and poverty, and the heavy work burdens of women all play a part in this respect. Children provide social standing for their parents as well as some prospect of economic support in old age. In the short term, children also can produce more than they consume. Women's time constraints and reduced availability of water and fuelwood have implications for infant and child health and mortality and, hence, on fertility aspirations and attitudes toward family planning. Where girls are kept out of school to help with domestic tasks, this negatively affects their fertility preferences and their ability to make knowledgeable decisions about family planning once they reach childbearing age. Polygamy and the widespread practice of women marrying at an early age and marrying considerably older men tend to increase women's eventual economic and social dependency on sons and, hence, their willingness to bear many children. The very young age at which women tend to marry increases the number of fecund years spent in union. In many traditional land tenure systems, as in open access systems, the amount of land allotted for farming is a function of the ability to clear and cultivate it – i.e., of family labor. The severe time pressure and the constraints faced by women in their farming and other income-earning activities may be preventing the emergence of women's demand for fewer children. There has been little progress in easing the constraints on women's productivity, their capacity to earn and control incomes, and their ability to assume greater control over their own fertility.

xiv. *Land and Tree Tenure Systems.* Traditional tenure systems in SSA, with communal land ownership, provide considerable tenurial security on land farmed by community members (although women's tenurial security is generally far less certain than that of men.) *Strangers* (i.e., non-members of the community) may obtain use rights, but usually with considerably less long-term security. As long as populations increased only slowly, traditional systems also were able to accommodate the emerging need to move towards *de facto* permanence of land rights assignment. Other aspects of traditional tenure systems have not adjusted rapidly enough to changing economic conditions. Often, the individual user's ability to transfer land use rights remains subject to significant constraints. Tree tenure arrangements are often distinctly separate from land use rights pertaining to the cultivation of annual crops, and this can result in serious conflict. Much common property land – forests, wetlands, and range lands – has become *de facto* open-access land and been converted to farming. In many areas where traditional land use rights provided for overlapping and complementary uses by sedentary farmers and transhumant herders, the development of valley bottoms into permanent crop land has created major constraints on the mobility of herders, with negative implications for environmental integrity. Increasing population pressure and agro-environmental problems are inducing considerable rural-rural migration. Since migrants often come with conflicting traditions of land allocation and land use, *strangers'* tenurial rights and their implications for land resource conservation are of increasing concern.

xv. Most governments and donors have mistakenly believed that traditional tenure systems provide inadequate tenurial security and that they could not adjust rapidly enough to changing demographic realities, agricultural technology developments and market forces. They also witnessed the erosion in customary laws and practices regulating land use which occurred as a result of significant rural-rural migration, changes in social values and customs, and ambiguities created by

the overlaying of "modern" land administration systems over traditional ones. In many instances, this led to the emergence of *de facto* open-access systems which are not conducive to resource conservation or to investments in soil fertility maintenance and land improvement.

xvi. Many governments have responded by nationalizing the ownership of land -- and then allowing customary rules to guide the use of some land, while allocating other land to private investors and public projects. Often, the well-connected have used their influence to wrest land from its customary owner-occupants. The result has been reduced, rather than improved, tenurial security. In most cases, this has accelerated the breakdown in customary land management and the creation of open access conditions, especially in forest and range areas, where settlement and exploitation by anyone are permitted and environmental degradation is invariably rapid. Where governments allocated individual land titles -- as in Kenya, Zimbabwe and Côte d'Ivoire -- this generally ignored the prior existence of customary tenure arrangements, and more often than not, the actual results have differed considerably from the stated intent. Local community and individual land resource management has been discouraged, while political and economic elites have succeeded in alienating the land from its traditional owners and users. This has skewed land distribution and intensified the exploitation of land resources for private short-term gain.

xvii. *Forest and Woodland Exploitation.* The heavy dependency on wood for fuel and building material has combined with rapid population growth to contribute to accelerating forest and woodland destruction. This is particularly severe around major urban centers where it has led to the appearance of concentric rings of deforestation. Fuelwood has generally been considered a free good, taken largely from land to which everyone has the right of access. This has impeded the development of efficient markets for fuelwood. Urban woodfuel prices reflect primarily transport costs, not the cost of producing trees, and there is no incentive to plant trees for fuelwood production until transport costs to urban markets become high enough to justify peri-urban planting. This is only beginning to happen around some cities and in very densely populated areas. Alternative fuels, such as kerosene or LPG, are more costly to obtain, not available in open-access conditions, and are therefore not replacing woodfuels in significant quantities.

xviii. Commercial logging has significantly contributed to deforestation. Although directly responsible for no more than 20 percent of forest destruction in SSA as a whole, it has been considerably more destructive in some countries, such as Côte d'Ivoire. Moreover, logging usually leads to a second phase of forest destruction: logging roads provide access for settlers who accelerate and expand the process of deforestation that the loggers have begun. Logging concessions rarely take into account the traditional land and forest use rights of forest dwellers. These rights, once eroded, are disregarded by new settlers penetrating along the logging roads.

xix. The degradation and destruction of forests and woodlands accelerates soil degradation and erosion, eliminates wildlife habitat, leads to loss of biodiversity, and has severe implications for local and regional climates and hydrological regimes. Deteriorating climatic and hydrological conditions negatively affect agriculture. The worsening fuelwood situation forces women and children to walk further and spend more time to collect fuelwood. Closely related, and increasingly of concern, is the fact that animal dung and crop residues are being used as fuels. Under conditions of shortening fallows, characteristic of much of SSA, their economic utility is far greater when they are used to maintain soil fertility. People also must walk further and/or pay more for building materials and the many important non-wood forest products they depend upon for medicinal purposes, home consumption and traditional crafts and industries. For forest dwelling people, forest destruction threatens not merely their lifestyles and livelihood systems, but their very survival.

D. An Action Plan

xx. The appropriate policy response and action program to address these problems are not obvious. Many of the most immediately attractive remedies have been tried and have failed. For example, individual land titling — intended to clarify resource ownership, prevent further degradation of common property regimes into de facto open-access situations, and improve tenurial security — has been tried in several countries and has been beset by significant problems. Similarly, efforts to introduce "modern" agricultural technology in the form of higher-yielding varieties, chemical fertilizer and farm mechanization have not met with great response from farmers. Soil conservation and forest protection efforts have had little success outside of relatively small areas. And efforts to slow population growth through programs based primarily on the supply of family planning services and the distribution of contraceptives have not been very successful in most SSA countries.

xxi. *Some Basic Targets.* Indicative aggregate targets regarding fertility rates, food availability, agricultural growth and environmental protection illustrate the magnitude of the effort required. Reaching these targets will be far more likely by focusing on the synergetic effects inherent in the linkages of the nexus. There are, of course, wide variations in what is necessary and attainable in each country, and country-specific targets will need to reflect this.

xxii. For SSA as a whole, agricultural production needs to grow at about 4 percent per annum during the period 1990-2020. Daily per capita calorie intake should be increased from the present average of 2,027 to about 2,400 by the year 2010. Although the share of the population that is food insecure should be reduced from the present 25 percent to zero as rapidly as possible, it is more realistic to aim for a reduction to 10 percent by the year 2010 and to 5 percent by 2020. The rate of deforestation needs to be slowed, and the area of forests and woodlands should be gradually stabilized. Loss of remaining wilderness areas should also be minimized: about 23 percent of SSA's total land area could be maintained as wilderness (compared with about 27 percent today). To preserve wilderness and forest areas, cropped land can only be increased from 7.0 percent of SSA's total land area at present to about 8.3 percent in 2020. The arithmetic of these indicative agricultural, food security and environmental objectives requires a reduction in population growth from the present average annual rate of over 3.1 percent to 2.3 percent per annum in the third decade of the next century. This will require lowering the average TFR by 50 percent between today and the year 2020.

xxiii. *Reducing Fertility Rates.* A key aspect will be to increase demand for fewer children. Increasing girls' school enrollment rates is critical. Better health care services and access to safe water will improve child survival rates and, hence, lower the demand for children. Educational efforts, directed at both men and women, are needed to raise awareness of the benefits of fewer children. Women's work loads need to be eased to reduce the need for child labor. Dynamic agricultural development and improved food security will also reduce the demand for children. Kenya, Zimbabwe, Botswana and Mauritius, where the TFR is declining, provide strong evidence. These countries have relatively high population densities on cultivated land, relatively high female school enrollment rates, relatively low infant mortality, active family planning (FP) programs, among the best performing agricultural sectors, and relatively good food security situations.

xxiv. As demand for reducing fertility rises, it must be effectively met with increased supply of FP services and contraceptives. But supply must follow demand — it cannot lead it. Where AIDS is a problem, improved health care, FP services and education focused on preventing sexually transmitted diseases and increasing the use of condoms become even more important.

xxv. *Promoting Environmentally Sustainable Agriculture.* Farm productivity per unit area must be raised significantly to generate more output with little increase in the area farmed. To minimize negative impacts on the environment, much more emphasis is required on "environmentally benign and sustainable" technologies. Land-saving technology will allow forests and other fragile areas to be protected. Numerous environmentally benign and economically viable agricultural techniques have been developed and successfully applied, often through adaptation of traditional practices that have evolved in response to local agro-ecological and socio-economic conditions. Examples include contour farming, minimum tillage, mulching, "managed" fallowing, numerous crop rotation and intercropping systems, vegetative and soil bunding, a variety of agro-forestry practices, integrated pest management, water harvesting and small-scale irrigation. Integrating livestock into farming systems and promoting animal traction will be important. Soil and moisture conservation needs to receive strong emphasis.

xxvi. Agricultural research and extension services need to focus less on mono-crop technologies and farm mechanization and much more on the above types of technologies, adapting them to local conditions and making them available to farmers in "menu" form for selective adoption. Women must become the target of such efforts to a much greater extent. These technologies are far more likely to find widespread acceptance by farmers. Prescriptive approaches to agricultural intensification are far less suitable in the varied environments of Sub-Saharan Africa – where conservation and management of natural resources, integrated production systems and risk management are critical – than in more homogenous high-potential regions such as the Indo-Gangetic Plain.

xxvii. However, intensification with the above technologies alone is unlikely to be sufficient in most SSA countries to achieve agricultural growth rates of 4 percent per year and more. Improved variety/fertilizer/farm mechanization technologies will also be necessary. Increased use of fertilizers will be especially important to raise yields and maintain soil fertility. So will diversification of production into higher-value crops, for domestic and export markets, to increase rural incomes and to improve food security through income stabilization. It would also be unrealistic, and unnecessary, to preclude bringing more land under cultivation.

xxviii. There has been little incentive for farmers to abandon their traditional practices. Intensive and resource-conserving agriculture must be made less risky and more profitable. This requires appropriate marketing, price, tax and exchange rate policies as well as investments in rural infrastructure, health and education facilities. Creating parks, reserves and community-owned range land and protecting these against conversion into crop land will be important to conserve natural resources and biodiversity. So will reducing infrastructure development in forests and other fragile areas to discourage settlement in these areas. Since this will limit the scope for further expansion of cropped land and, potentially, the scope for agricultural production growth, there is a trade-off between conservation and agricultural growth. Creating additional protection areas will only be feasible and sustainable if agricultural production can be intensified at the rate suggested here (i.e., to about a 3.5 percent annual increase in farm output per unit of land farmed). In this sense, conservation and agricultural intensification are complementary. As African farmers have shown, land scarcity leads to agricultural intensification – and if the necessary advice and inputs are available, intensification can be made sustainable and the rate of intensification greatly accelerated. Strengthening tenurial security will also stimulate greater concern for soil fertility management and conservation as well as tree planting. Some sustainable agricultural practices, such as soil conservation, may require initial subsidization to offset externalities.

xxix. *Easing Women's Time Constraint and Improving Their Productivity.* Initiatives in research, extension, infrastructure development, rural technology, and education are needed to ease women's time constraints and improve their productivity. Much can be learned in this regard from the experience of local and international NGOs in establishing rural water supply systems managed by women's groups, developing and popularizing locally appropriate fuel-efficient and time-saving stoves, providing improved farming and crop processing techniques and tools to women, facilitating women's access to land and institutional credit, improving village-level transport infrastructure, and providing intermediate means of transport. Such initiatives should be pursued through projects dealing with agricultural research and extension, rural water supply and transport, credit and land tenure, and in education and training policies which more effectively reach women.

xxx. *Clarifying Resource Ownership.* Urgent action is needed to eliminate open-access systems and to provide legal protection to traditional and private land owners. Local community or individual ownership and management responsibility of natural resources appear to be the only workable arrangement in Sub-Saharan Africa. Governments alone are not able to protect and conserve land, forest and pasture resources. State-ownership of farm land should be eliminated. Where traditional tenure arrangements continue to work and are evolving toward explicit recognition of individual ownership and transfer rights, these systems should be recognized and protected by law and supported by appropriate administrative arrangements. Land title should be provided to traditional communities, and community land can continue to be allocated according to customary practice. Where traditional mechanisms have completely broken down, individual land titling is likely to be necessary, but it should be provided only on demand and to the traditional or customary owners/occupants. Women need equal rights to land and equal tenurial security as men, especially in view of the increasing number of female heads of households in many rural areas. These actions will require effective mechanisms to assess land ownership and to ensure legal protection to holders of either traditional or modern titles.

xxxi. Wherever possible, state-owned pasture and forest lands should be returned to traditional owners and/or local communities, with clear and legally established utilization rights tied to the responsibility for conservation. This must be done with care, however, since many of these communities and their traditional land resource management systems have broken down under the pressure of logging, settler influx, and Government ownership. Where this is the case, resource destruction may simply accelerate if people are given the opportunity. Communities will need appropriate technical assistance in managing these resources.

xxxii. *Addressing the Fuelwood Problem.* Efforts to promote agro-forestry need to be greatly expanded to have a significant impact on the agro-ecological environment, the rural energy economy and women's time. Investment in fuelwood production and tree farming, on a large scale, by farmers and by community groups and private enterprises will not occur unless it is profitable. The incentives are gradually emerging, particularly around major urban areas, as populations grow and forests and woodlands are depleted. But woodfuel markets are developing too slowly, impeded by inappropriate forest, land tenure and energy policies. The pace of market development will be accelerated if open-access sources of fuelwood are eliminated, cutting in protected areas is restricted, farmers are not restricted or taxed in marketing wood from their own land, fees are levied on bringing fuelwood to urban centers so as to provide incentives for wood production near cities, and communities and farmers have uncontested ownership of local forests and woodlands. On the demand side, there is a great need for more fuel- and time-efficient wood and charcoal stoves which can be made by women themselves or by local artisans on a commercial basis.

xxxiii. ***Infrastructure Development and Settlement Policy.*** The importance of rural infrastructure and of rural towns and secondary cities for promoting agricultural and rural development is well established. Many services provided to rural communities are provided from secondary towns and cities. They also provide the major wholesale markets for agricultural products on their way to major cities and to the ports, as well as the assembly markets for agricultural inputs and consumer goods going to rural areas. The strong bias in urban and infrastructure investments favoring the few major cities needs to be abandoned. Adequate transport links to product markets are major factors associated with the intensification of farming – even where population densities are comparatively low. The high physical barriers and economic costs of transporting goods to local markets sharply reduce farmers' incentives to switch from subsistence to market production and from extensive to intensive farming. Rural roads and improved tracks navigable for animal-drawn vehicles are crucial. Major efforts are also needed to promote the use of locally suitable and appropriate intermediate transport technology, especially animal-drawn implements, and of improved off-road transport.

xxxiv. Infrastructure development also has a major impact on the productivity of rural labor and on key determinants of fertility. Roads provide access to health facilities and schools. Water supply and sanitation facilities have significant impact on health and labor productivity. Rural water supply, sanitation, health and education facilities and services are particularly important in terms of their impact on infant and child mortality and on female education – both critical determinants of fertility preferences.

xxxv. Careful locational targeting of infrastructure and urban development can also be a powerful instrument to guide population movement into environmentally resilient areas with agricultural potential and to keep settlers out of fragile areas.

xxxvi. ***Natural Resource Management and Environmental Protection.*** Environmental resource protection and sustainable management are urgently needed to prevent further degradation and destruction. Establishing conservation areas and protecting forests is conducive to promoting agricultural growth, because they protect watersheds, stabilize local and regional climate and hydrological systems. If the rate of agricultural intensification can be increased as postulated here, the constraining impact of expanding conservation areas on crop land expansion can be offset and conservation will be fully consistent with agricultural growth. Protection of rural environments also ensures the sustainable provision of crucial forest products and environmental services. Particularly urgent are establishment and maintenance of conservation areas and effective regulation and taxing of logging. Environmental Action Plans are a suitable instrument to plan these and other actions in a coherent manner. Reconciling objectives of natural resource management, settlement and population policy, agricultural and infrastructure development can be accomplished in regional and local land use plans. Local communities and individuals need to be directly involved in the development and implementation of such plans, and they must have ownership of natural resources to manage and conserve these. Mobilization of community and individual participation in natural resource management may be the most important step now waiting to be taken.

xxxvii. Land use plans should identify areas to be protected, areas to be farmed, areas to be utilized for sustainable logging, and so forth. Land allocation and use, land tenure systems, agricultural technology, infrastructure development, and conservation efforts must be tailored to the specifics of each region and location. Land use planning is a useful tool for reconciling objectives of natural resource management, settlement and population policy, agricultural and infrastructure development. These objectives come together in specific locations and can be effectively integrated in regional and local land use plans. Most important will be the empowerment of local communities

to manage natural resources and their involvement in the development and execution of these plans. Communities and individuals must have ownership of natural resources if they are to manage and conserve them properly. Mobilization of community and individual participation in natural resource management may be the most important step now waiting to be taken.

xxxviii. In the final analysis, however, successful agricultural intensification and much reduced fertility rates and population growth are the critical elements to preventing further degradation of the rural environment.

E. Conclusion

xxxix. Past efforts have, on the whole, failed to reverse the direction of the downward spiral that is driven by the synergetic forces of this Nexus. Part of the explanation appears to be that past efforts have been pursued too narrowly along traditional sectoral lines – matching established institutional arrangements and traditional academic disciplines – while crucial cross-sectoral linkages and synergies have been ignored. At the same time, primary emphasis in most sectoral development efforts has generally been placed on the supply side, i.e., on efforts to develop and deliver technology and services). Far more emphasis needs to be placed on promoting effective demand for environmentally benign farming intensification technologies, for family planning services, for resource conservation. The synergies inherent in the Nexus provide considerable potential in this regard. To address these issues requires appropriate cross-sectoral analysis and the development of action programs which address the linkages and synergies among them. Action, however, should be defined within single sectors to facilitate efficient implementation.

xl. In analytical work that should precede the formulation of action plans and, particularly, of developmental interventions, far greater attention needs to be paid to the social organization of production and consumption, of decision-making and resource allocation, of access to resources and services. These systems and structures can be very complex and often differ substantially among communities. This implies the need to use relevant "units of analysis." The "household", the "family" and the "family farm" may not be appropriate if these terms are simply assumed to convey concepts of social and economic arrangements familiar to 20th-century industrialized economies. Where societies are characterized by complex resource-allocation and -pooling arrangements for both production and consumption purposes, based on lineage, kinship, gender and age-groups, it is imperative to be cognizant of these, to analyze the impact of development interventions on individuals in this context, and to design development efforts such that traditional groups can implement and manage them. Gender issues are particularly critical, especially in terms of gender-specific divisions of responsibilities, tasks and budgets, as well as in terms of access to resources, information and markets. Interventions and incentives do not necessarily work in the same direction or with the same intensity for men and women.

xli. Already, many SSA countries have begun to implement various elements of this action plan. Over 20 national environmental action plans are in place or being prepared. Several country-specific population, agriculture and environment nexus studies have been initiated, including in Côte d'Ivoire, Malawi, Nigeria, Rwanda and in the Sahelian countries as a group. Macroeconomic and agricultural policy reforms are underway in over half the African countries. Several countries have successful family planning programs, and others are developing promising programs. Agricultural research and extension systems are beginning to place more weight on "sustainable" technology and responsiveness to varying farmer demand. A few countries have brought much of this together and obtained positive synergies between agricultural growth, environmental protection and reduction in fertility rates. Kenya, Zimbabwe, Botswana and Mauritius are examples. Others, such as Ghana and

Tanzania, are moving in the right direction. Major deficiencies remain in rural health care and education (particularly female education), rural infrastructure, promoting more participation of local communities in development efforts, forest and conservation policy, land tenure reform, urbanization policy, and family planning programs. The distance to travel is long, but the way to go is clearer.

I. INTRODUCTION AND HYPOTHESES

A. Objectives of the Study

1.1 Over the past thirty years, most of Sub-Saharan Africa (SSA) has experienced very rapid population growth, slow agricultural growth and severe environmental degradation. Increasing concern over these trends and the failure of past efforts to reverse them has led to the decision to review the available research findings and operational experience. The objective of this study is not to compile and address all of the demographic, agricultural and environmental issues facing the countries and people of Sub-Saharan Africa. It is, rather, to gain a better understanding of the linkages and mutually reinforcing causes of these three sets of problems. The demographic, agricultural and environmental problems are closely interlinked in a "nexus" of multiple and mutually reinforcing causality chains.

1.2 The need to survive -- individually and as a species -- affects human fertility decisions. It also determines people's interactions with their environment, because they derive their livelihood and ensure their survival from the natural resources available and accessible to them. Rural livelihood systems in Sub-Saharan Africa are essentially agricultural, and agriculture is the main link between people and their natural resource environment. Through their agricultural activities, people seek to husband the available soil, water and biotic resources so as to "harvest" a livelihood for themselves. Such harvesting should be limited to the yield sustainable from the available stock of resources in perpetuity so as to ensure human survival over successive generations. Improvements in technology can make the use of these resources more efficient -- increase the sustainable yields and/or reduce the resource stock required. Population growth should, thus, be matched or surpassed by productivity increases so as to safeguard the dynamic equilibrium between the available/required stock of resources and the human population that depends on it for survival. Over the past thirty years, this has not been the case in Sub-Saharan Africa. The rate of population growth has considerably exceeded the rate of productivity increase in agriculture -- and this has resulted in the "mining" of natural resources as well as in stagnating per capita agricultural production and incomes. Why this has occurred, and what can be done about it, are the questions addressed in this study.

B. The Nexus: An Hypothesis

1.3 This study's hypothesis is that there are strong synergies and causality chains linking rapid population growth, degradation of the environmental resource base, and poor agricultural production performance -- the "nexus". Key linkages are likely to be found in traditional African crop production and livestock husbandry methods, traditional land tenure systems and land use practices, traditional responsibilities of women in rural production and household maintenance systems, and traditional methods of utilizing woodland and forest resources. These systems and practices were well suited to survival needs on Africa's fragile resource endowment when population densities were low and populations stable or growing only slowly.

1.4 As Ester Boserup pointed out, farmers are unlikely to intensify their mode of production (i.e., to produce more output per unit of land) unless there is a constraint on the amount of land available for farming with low labor and low capital inputs (Boserup, 1965). Technological innovation at the farm level comes about at least in part because of farmers' inability to carry on with traditional technologies and still ensure an adequate livelihood. Extensive agricultural production systems -- shifting and long-fallow cultivation and transhumant pastoralism -- are the appropriate responses to abundant land, limited capital and limited technical know-how. They have predominated

in most of Sub-Saharan Africa where, into the recent past, they been the optimal modes of production for farmers and herders.¹ Where population density gradually increased over time, traditional systems of cultivation, land tenure, women's responsibilities, and forest resource use evolved in response. This evolution was slow -- matching the rate of population growth and, hence, the pace of adjustments required.

1.5 These well balanced and slowly evolving traditional systems came under increasing strain with the rapid acceleration of population growth that began when mortality rates started to decline sharply in the 1950s while birth rates remained high. The traditional arrangements and practices, so well suited to an Africa of low population densities, failed to evolve fast enough. The unprecedented rate of population growth in the past few decades has placed a severe strain on the traditional rural production and livelihood systems in Sub-Saharan Africa. The pace of evolution in key elements of these systems -- farming practices and technology, land tenure and management arrangements, women's responsibilities, forest resource utilization -- has been inadequate in the face of the dramatically intensifying pressure of more people on finite stocks of natural resources. Traditional land use and wood provision practices have become major direct causes of environmental degradation and resource depletion. This degradation reduces the productivity and resilience of natural resource systems, contributing to soil erosion and changing weather patterns, which then contributes to agricultural stagnation and, in turn, impedes the onset of the demographic transition.

1.6 Chapter II documents key consequences of this process. These include rapid and accelerating deforestation, widespread problems of soil erosion and fertility loss, and rising population growth rates. The growth of agricultural production, on the other hand, remains at its approximate long-term average of about 2 percent per annum, falling well short of population growth. The results include widespread food insecurity, poor export earnings, and little stimulus from the agricultural sector for overall economic development and growth.

1.7 Sub-Saharan Africa's forest cover has been diminishing at a rate of more than 0.5 percent per year in the 1980s. Forests provide many products and serve many functions, and these are diminished or lost with deforestation. Vast areas of farmland are affected by soil erosion, and vast portions of Sub-Saharan Africa's pasture and range areas show signs of degradation. Degraded soils lose their fertility and water absorption and retention capacity, with drastic effects on vegetative growth. Significant declines in rainfall are being recorded in many countries and are at least partly attributable to the rapid destruction of forests. This environmental degradation has a negative impact on crop and livestock production and on water availability for human and livestock use. Since 1965, the increase in agricultural production in Sub-Saharan Africa has averaged only about 2 percent per year, while the total population has grown at about 2.8 percent annually. In the 1980s, agricultural growth has been only slightly above the longer-term average, but the rate of population growth accelerated to about 3.1 percent per year. Nowhere and at no time in history has any significant human population grown at such a rate. Per capita food production has declined in many countries, and roughly 100 million people in Sub-Saharan Africa are food insecure. Average per capita calorie consumption has stagnated at very low levels and declined in some countries. The average African consumes only about 87 percent of the calories needed for a healthy and productive life. Poor agricultural performance is due in large part to the poor policy environment for agriculture, but much of the explanation also lies in environmental degradation, in the continuous expansion of farming into areas only marginally suited to crop farming, and in the lack of adaptation of various improved agricultural technologies to the locally prevailing agro-ecologic and socio-economic conditions.

¹ See, for instance, Pingali, Bigot and Binswanger, 1987; Lele and Stone, 1989.

1.8 The human costs associated with this forest and land degradation are substantial. As forests and woodlands are destroyed, people must walk further and/or pay more for fuelwood, building materials and the many important non-wood forest products they depend upon. Woodfuels are the staple source of household energy in Sub-Saharan Africa, and the demand for woodfuels is rising at about the rate of population growth. As fuelwood becomes scarce, women and children have to spend more time collecting it from more distant sources. Since forests recycle considerable quantities of water locally, deforestation also has negative effects on local and regional rainfall and hydrological systems. Combined with deteriorating soil structure, which reduces the water absorption and retention capacity of the soil and, thus, groundwater recharge, this leads to declining plant growth and worsening rural water supply for both humans and animals. Women have to go further, especially during the dry season, to fetch water for household use as well as for watering livestock and home gardens. And forest destruction threatens not merely the traditional lifestyles and livelihood systems, but the very survival of forest dwelling peoples.

C. Critical Linkages

(i) Shifting Cultivation and Transhumant Pastoralism

1.9 Chapter IV deals with the most important linkage in the process hypothesized above. For centuries, shifting cultivation and transhumant pastoralism have been, under the prevailing agro-ecological conditions and factor endowments, appropriate systems for people throughout most of Sub-Saharan Africa to derive their livelihood in a sustainable manner from the natural resource endowment of their environment. The ecological and economic systems were in equilibrium. The key to maintaining this equilibrium was mobility: people shifted to a different location when soil fertility declined or forage was depleted, allowing the fertility of the land to be reconstituted through natural vegetative growth and decay. For field cropping, this typically involved cultivation periods of two to four years, land then being left fallow for as long as 15 to 25 years. Herders' mobility generally involved a far greater geographic range, but a far shorter temporal cycle: they would move their herds on extended migratory patterns as dictated by the seasonal availability of water and forage and in most cases repeat the same cycle in one or sometimes two years. Adjustments to these traditional systems, including gradual intensification of farming practices, took place as and when they became necessary, but the pace of the adjustment required was slow.

1.10 As long as population growth was slow and land remained available, the additional people could be accommodated by gradually bringing more land into the farming cycle. But new land for cultivation has become increasingly scarce in most regions of Sub-Saharan Africa. Large areas of forests, wetlands, river valley bottoms and savanna have been converted to farmland. The scope for further expansion has drastically narrowed. There is considerable diversity among countries – but everywhere fallow periods are becoming shorter as populations increase and the land frontier recedes. In many areas, such as Mauritania, Kenya, Rwanda, Burundi, Lesotho and Liberia, fallow periods are no longer sufficient to restore soil fertility. Increasingly, rural people are compelled to remain on the same parcel of land, due to the lack of availability of unoccupied land – yet they retain their traditional farming methods.

1.11 These people are faced with a critical dilemma. The most central element of their traditional farming system – the ability to shift around on the land – is being eliminated by population pressure, yet they continue to use the other elements of this traditional production system. Soil fertility is not restored and soils are not conserved where fallow periods are too short, or non-existent, and where traditional cultivation techniques continue to be used. As a result, crop yields decline and soils erode. When farming is no longer viable, people migrate to establish new farms

on land previously not used for farming -- in semi-arid areas and in tropical forests where soil and climatic conditions are poorly suited to annual cropping. The process of indigenous adjustment has been too slow in the 1970s and 1980s to keep pace with the unprecedented rate of population growth and population movement. The result has been low growth, and in some cases decline, in crop yields. Population pressure is inducing farmers to intensify production, but for the most part this is occurring much too slowly to offset the negative impact on crop fertility.

(ii) Land and Tree Tenure Systems

1.12 A second link, also discussed in Chapter IV, involves land tenure systems. Traditional systems provide considerable security of tenure on land brought into the farming cycle (clearing, cropping, fallowing, reclearing) through customary rules of community land ownership and allocation of use rights to members of the community. In most cases, the tenurial security enjoyed by members of the community is sufficient to induce investment in land. Outsiders, or *strangers* (i.e., non-members of the community) may obtain use rights of various types, but in many cases with considerably less long-term security. As long as populations increased only slowly and the demand for land use rights by migrants from other communities remained modest, traditional systems also were able to accommodate the emerging need to move towards *de facto* permanence of land rights assignment to community members.

1.13 With increasing rural-rural migration and settlement in previously less densely populated areas, *strangers'* tenurial rights and their implications for land resource conservation are of increasing concern (migrants in most cases being *strangers* in the areas to which they move). Tree tenure arrangements are often distinctly separate from land use rights pertaining to the cultivation of annual crops and can result in serious conflict. And traditional norms have increasingly failed to provide adequate protection to land that is not already in the farming cycle and, hence, not under individual or family management. On the contrary, with rapidly growing populations and associated demand for bringing new land into cultivation, common property land -- such as forests, wetlands and range lands -- has often become *de facto* open-access land. Finally, in many areas where traditional land use rights provided for overlapping and complementary uses by sedentary farmers and transhumant herders, rapid population growth and the conversion of valley bottoms into permanent farm land has created major constraints on the mobility of herders, with serious implications for environmental integrity.

1.14 Most governments and donors have mistakenly believed that traditional community ownership of land is totally inconsistent with individualized tenurial security. Traditional tenure systems did not seem to adjust rapidly enough to changing demographic realities, agricultural technology developments and market forces. Governments and donors also witnessed the erosion in customary laws and practices, including those regulating land use. This erosion occurred partly as a result of significant migration within and between many countries, partly as a result of changes in social values and customs, and partly as a result of ambiguities created by the overlaying of "modern" land administration systems over traditional ones. The result, in many instances, has been the emergence of *de facto* open-access systems which are not conducive to resource conservation or to investments in soil fertility maintenance and land improvement. Such open access systems, found especially in forest and pasture areas, result in rapid environmental degradation -- following the script of the "tragedy of the commons". Each user has an incentive to exploit the land and the associated resources as much as possible for private advantage, moving on when the resources are exhausted or too depleted to provide a livelihood. Moreover, in open access systems the size of land holdings is partly a function of the amount of family labor available; this may be an important element contributing to the high fertility preferences observed.

(iii) Women's Time and Their Role in Agriculture and Rural Production Systems

1.15 A third critical link is the important role of women in rural production systems, dealt with in Chapter V. The widespread prevalence of gender-specific (gender-sequential and/or gender-segregated) roles and responsibilities in rural production systems may be a major factor contributing to agricultural stagnation and environmental degradation as well as to the persistence of high fertility rates. In many areas, women have primary or sole responsibility for food crop production, and they usually manage separate fields for this purpose. Women also tend to have significant obligations concerning labor to be performed on men's fields and with post-harvest processing activities.

1.16 Given women's triple roles – child bearing and rearing, family and household maintenance, and production and income-earning activities – the pressures on their time continue to intensify. With increasing deforestation, yet growing populations requiring more fuelwood, fuelwood has become scarcer, and women must walk further to fetch it – or reduce the number of hot meals prepared. Increasing populations put greater pressure on available water resources, while environmental degradation reduces the availability and accessibility of water. Women must walk further to fetch water, and get their daughters to help them. Throughout much of rural Sub-Saharan Africa, women also are the primary providers of transport services. In the absence of adequate rural transport infrastructure and of means of transport other than human portorage, women spend substantial time headloading water and fuelwood, farm produce and other commodities.

1.17 As growing numbers of working-age men leave the farms to work in towns and cities, women are increasingly taking on primary responsibility for farm operations – while their access to adult male labor for critical tasks is diminishing. Moreover, the expansion of higher-input cash cropping under male control tends to increase demands on female labor for traditional female activities such as weeding and harvesting. At the same time, women in most societies are confronted with severe restrictions on access to land, to extension advice, to institutional credit, and to improved production, processing and transport technology. These constraints, combined with the intensifying pressures on women's time, severely impede productivity improvements and the intensification of women's farming operations. As a result, most women farmers have little choice but to continue practicing traditional low-input, low-productivity farming which, with sharply shortened fallow periods, is neither environmentally sustainable nor viable in terms of longer-term agricultural productivity. Women's time constraints also retard the growth of cash crop production controlled by men, since this depends on substantial female labor input at critical times.

1.18 The constraints on women's time have implications also for infant and child welfare and, hence, infant and child mortality – with significant repercussions on fertility aspirations and attitudes toward family planning. More contentious is the hypothesis that the multiple work burdens and the heavy time pressure on women, by raising demand for child labor, may contribute to the persistence of high fertility rates. Additional labor may be the only factor of production which women can easily augment, or are permitted or even compelled to augment, in order to meet their production and household management responsibilities. The traditional role of women may thus be contributing to maintaining the extraordinary fertility rate in Sub-Saharan Africa (the total fertility rate, TFR, is the total number of children the average woman has in a lifetime), now equal to about 6.5 (compared with 4 in all developing countries taken together).

(iv) The Rural Energy Economy and Traditional Fuelwood Provision

1.19 Fuelwood provision and use are important issues in terms of women's time and productivity as well as in terms of environmental degradation. Closely related is the fact that animal

dung and crop residues are increasingly being used as fuel, although not yet to the degree found in South Asia. The economic utility of using such organic matter to maintain soil fertility under conditions of shortening fallows and the gradual shift to permanent cultivation is very high, and its declining availability for this purpose has a high cost in terms of reduced agricultural productivity.

1.20 The heavy dependency on wood for fuel and building material has combined with rapid population growth to contribute to accelerating forest and woodland destruction. This is particularly severe around major urban centers where it has led to the appearance of concentric rings of deforestation. Wood is generally regarded as a free good, taken largely from land to which everyone has the right of access. As a result, efficient markets for fuelwood have not developed in most countries – despite its increasing scarcity. Consumer prices reflect primarily the cost of transporting the wood, not the cost of tree planting and maintenance. Even where extreme scarcity has led to the emergence of an efficient market, the price of fuelwood has been below the cost of replanting because most supplies come from open-access sources. Alternative fuels, such as kerosene or LPG, are more costly to obtain. Despite dwindling supplies of wood for fuel and building material, other fuels are therefore not replacing woodfuels (and other biomass such as dung and crop byproducts) in significant quantities.

1.21 The degradation and destruction of forests and woodlands through unsustainable woodfuel extraction accelerates soil degradation and erosion, causes destruction of wildlife habitat, leads to loss of biodiversity, and has severe negative implications for local and regional climates and hydrological conditions. Deteriorating climatic, soil and hydrological conditions negatively affect agriculture. There is further feedback to the Nexus through the increasing burden on women who must walk further and spend more time to meet household fuelwood needs or, in situations of extreme scarcity, are forced to cook with dung or crop residues or even to reduce the number of cooked meals.

(v) Logging, Forest Management, and Settler Influx into Forest Areas

1.22 In forested regions, logging has contributed to rapid reductions in the area under forest cover, with similar negative impact on climatic patterns and soil fertility as excessive and unsustainable woodfuel extraction. Although directly responsible for no more than 20 percent of forest destruction in Sub-Saharan Africa as a whole, it has been considerably more destructive in some countries, such as Côte d'Ivoire. However, commercial logging usually leads to a second – and in most cases far more damaging -- phase of forest destruction. Logging roads provide access for land-hungry settlers into areas previously difficult to enter, and these settlers accelerate and expand the process of deforestation that the loggers have begun. Logging concessionaires ordinarily acquire rights to log from governments, without regard to the traditional rights of forest dwellers. These rights, once eroded, are not respected by new settlers penetrating along the logging roads.

(vi) Interaction With Policy Constraints and Other Structural Problems

1.23 Many other factors also have a detrimental impact on agriculture and the environment. These include civil wars, inappropriate price, exchange rate and fiscal policies, poor rural infrastructure, lack of private investment in agricultural marketing and processing, and ineffective agricultural support services. These were discussed in the World Bank's recent report on Sub-Saharan Africa's development perspectives (World Bank, 1989d). By preventing significant gains in agricultural productivity and contributing to the persistence of rural poverty, these factors compel growing populations, as a survival strategy, to exploit ever more extensively the natural resources available and accessible to them. Continued predominance of long-fallow cultivation and of traditional farming methods, traditional separation of farming activities into male and female spheres,

and unsustainable methods of forest resource exploitation will continue in these circumstances. A necessary condition for overcoming the problems of agricultural stagnation and environmental degradation will be, therefore, policy improvements along the lines suggested in the above World Bank report.

D. Population Growth Revisited: Feedback from the Nexus

1.24 Agricultural stagnation and environmental degradation probably inhibit the demographic transition because they retard economic development which is the driving force behind this transition. The extraordinarily high fertility rates prevailing in Sub-Saharan Africa are the result of many factors. The fundamental problem is low demand for smaller families. In many societies, becoming a parent is a precondition for becoming a socially recognized adult. Fertility enhances female and male status, while infertility results in severe anxiety and, particularly for women, can be socially and economically devastating. Such widespread phenomena as polygamy and women marrying considerably older men tend to increase women's eventual economic and social dependency on sons and, hence, their willingness to bear many children. The very young age at which women tend to marry increases the number of fecund years spent in union.

1.25 Infant and child nutrition and mortality are affected by the availability of safe potable water and by the number of nutritious and warm meals provided. Where environmental degradation reduces the availability and accessibility of water and fuelwood, this has negative impact on infant and child mortality and, hence, positive impact on parental demand for more children. Where girls are kept out of school to help with domestic tasks, including water and fuelwood fetching, this has strong negative repercussions for their fertility preferences and their ability to make knowledgeable decisions about family planning once they reach childbearing age. Where food security is low, demand for children remains high -- so as to provide labor to help produce more food ("each mouth comes with two hands attached to it") and to ensure the survival of some children for providing support in one's old age.

1.26 The preference for many children is also linked to economic considerations. In many communal land tenure systems, the amount of land allotted for farming to a family by the community (through its chief or its *chef de terre*) is a function of its ability to clear and cultivate land -- i.e., of family size or, more correctly, family labor (hired labor in most settings being rare, although labor pooling for certain tasks is not uncommon). This is also true in open-access systems where the size of holdings equals land cleared and cultivated. This counteracts efforts to stimulate demand for fewer children. Moreover, as long as there is (or is perceived to be) as yet unfarmed and unclaimed land available, there is no incentive for individuals to manage their land more intensively nor to limit their family size so as to be able to bequeath a viable farm to their offspring.

E. The Evidence

1.27 This study presents the evidence for the complicated inter-actions identified above. Chapters VI to X outline an action program to deal with these problems in a manner which exploits the positive synergies between agricultural intensification, reduced population growth and environmental resource conservation. The action program involves elements that are relatively new. It also presents much that is well known, such as the need for far greater attention to gender issues, from a new perspective. The evidence on which the analysis and recommendations are based is largely from site-specific studies. Given data limitations, statistical analysis, though attempted and presented, does not provide definitive confirmation. Statistical analysis and country level studies are therefore continuing.

II. AGRICULTURAL STAGNATION AND ENVIRONMENTAL DEGRADATION

A. Agricultural Stagnation, Population Growth and Food Security

2.1 Over the past 25 years, agricultural production in Sub-Saharan Africa rose by only about 2 percent a year, while aggregate population growth averaged about 2.8 percent per year (Tables 2 and 9).¹ Per capita food production has declined in most SSA countries (Table 10). Food imports increased by about 185 percent between 1974 and 1990, food aid by 295 percent. But the food gap (requirements minus production) -- filled by imports, or by many people going with less than what they need -- is widening. In the early 1980s, about 100 million people in Sub-Saharan Africa were unable to secure sufficient food to ensure an adequate level of nutrition for themselves, and average food consumption per capita has declined during the 1970s and 1980s in 17 of the 36 SSA countries for which data are available (Table 10).² In years of poor harvests the numbers affected have been much larger. Severe food shortages were exceptional in the 1960s, but are no longer so. Famines in several countries in the 1980s have been graphic indications of natural calamity, as well as of civil disruption, in the region. On average, officially estimated per capita food intake in Sub-Saharan Africa in the late 1980s, at 2,027 calories per day, was actually below the 1965 level and significantly lower than in other parts of the developing world. The average in India, for example, is 2,238 calories daily per person. The average African consumes only about 87 percent of the calories needed for a healthy and productive life.

2.2 The available data show no acceleration of aggregate agricultural growth in the 1980s. It has only slightly risen above the longer-term average for the past three decades of 2 percent per annum (Table 9). (It was higher than 2 percent in the 1960s and much lower in the 1970s.) This poor performance is also evident in the decline of agricultural export earnings. Export volumes and values have declined for almost all SSA countries (Table 13). There are notable exceptions. Exports of tea and horticultural products from Kenya, cocoa from Côte d'Ivoire and cotton from several West African countries have grown substantially in volume. But the success stories are few.

2.3 Projections, based on present trends, are disturbing. Aggregate population growth has accelerated to over 3.1 percent per annum (Table 2). Present projections, based on current trends in fertility and mortality rates (including the impact of AIDS), indicate only a slight deceleration in aggregate population growth through the year 2000. The total fertility rate (TFR) -- i.e., the average number of children born to a woman in her childbearing years -- for Sub-Saharan Africa as a whole has remained at about 6.5 or 6.6 from 1965 to the present (Table 2). By contrast, the average TFR for all the world's low-income countries declined from 6.3 in 1965 to 4.0 in 1987. During the same period, the crude death rate in Sub-Saharan Africa fell from 23 to 16 (Table 3). In countries with a high incidence of AIDS, death rates will rise, but nowhere is population growth expected to fall below 2 percent per annum by the year 2000, even under worst-case AIDS scenarios currently

¹ Statistical information on agricultural performance, as on most other aspects of social and economic development, are difficult to obtain and tend to be of poor quality. A considerable effort was made in this study to draw on what is generally assumed to be the best available statistical information (see the Statistical Appendix for data and sources).

² It is widely recognized that the data on which food availability and consumption estimates are based (e.g., crop acreage, yields, livestock production, processing and storage losses, etc.) are of poor quality in most African countries. Increasingly, it is also recognized that non-cultivated plants and "bushmeat" contribute far more to many Africans' diets, particularly in poor crop years, than has been captured in official statistics. Nevertheless, few observers are as skeptical of the general picture of serious food deficits as Svedberg (1991).

considered plausible.³ Unless efforts to reduce TFRs succeed (or mortality rates rise dramatically due to currently unanticipated AIDS developments), population growth rates will decline very little.

2.4 Table VI.I (pg. 63) shows the implications of these trends for Sub-Saharan Africa's future food gap. In 1990, Sub-Saharan Africa's 494 million people produced about 90 million metric tons of maize equivalent of food. With 100 million tons of aggregate consumption, there was a gap of 10 million tons met by imports. At currently projected growth rates, Sub-Saharan Africa's population will total about 1,200 million and its food production will reach about 163 million tons of maize equivalent in 2020. Aggregate requirements will be about 243 million tons, assuming there is no change in average per capita consumption. The 80 million ton food gap would be eight times today's gap and equivalent to about one fourth of the present annual production of cereals in the United States. Food aid varied between 4 and 7 million tons of cereals per year in the 1980s and could not conceivably increase sufficiently to fill this gap. Without significant per capita growth in agricultural production it is difficult to imagine sufficient overall economic growth that would generate the resources needed to finance food imports of this magnitude -- nor, for that matter, to maintain educational and health services and infrastructure facilities.

2.5 These disturbing trends will, of course, not continue indefinitely. What is at issue is how they will eventually be overcome. Will the strong synergies and the dynamics of these trends lead to human and environmental degradation and ultimately to widespread starvation? Or will these trends be overcome through voluntary, but determined action to reduce population growth and promote sustainable agricultural development and growth?

B. The Deteriorating Natural Resource Base and Ecological Environment

2.6 Much of Sub-Saharan Africa's natural resource base and ecological environment are deteriorating. If present trends continue, they will deteriorate even more rapidly in the future. The most pressing problem is the high rate of loss of vegetative cover -- mainly due to deforestation and conversion of savanna to crop land -- which in turn leads to loss of soil fertility and soil erosion. Global and regional climatic changes and/or deviations from longer-term average conditions are also causal factors -- but human impact on the environment in Sub-Saharan Africa may itself be an important element contributing to these climatic changes.

(i) Deforestation

2.7 In much of Sub-Saharan Africa, deforestation is a major problem -- with significant local, national and global consequences. Forests provide a multitude of products and serve many functions, including essential environmental ones. With deforestation, these are lost. Forests and woodlands are cleared for farming and logged for fuelwood, logs and pulp wood. Data on forest resources and rates of extraction and clearing are imperfect, as are data on most of Africa's environmental resources, but information is continually improving and reliable enough to suggest the scale of the problem. In 1980, there were about 679 million ha of forests and woodlands in Sub-Saharan Africa. A 1980 FAO/UNEP study estimated that 3.7 million ha of tropical Africa's forests and open woodlands were being cleared each year by farmers and loggers (Lanly, 1982). More recent estimates suggest that close to 3.8 million ha have been lost each year during the 1980s (Table 18),

³ Demographic modeling of the potential impact of AIDS is extremely difficult. Some simulations suggest that AIDS may reduce the population growth rate of SSA as a whole by as much as 0.5 to 1.0 percentage points in the early decades of the 21st century -- through drastically higher mortality rates. But higher mortality rates may delay fertility declines.

mainly through conversion to farm land, and the rate of deforestation may be accelerating. Reforestation amounted to only 229,000 ha per year during the 1980s, only about 6 percent of the area lost each year to deforestation (Table 18).

2.8 Aggregate data obviously obscure important differences among regions and countries. Deforestation has been particularly rapid in West Africa, with Eastern and Southern Africa also suffering substantial losses in forest cover.⁴ Large tracts of tropical forest still remain, especially in Zaïre, Gabon, Congo, the Central African Republic and Cameroon. It would take many years for Central Africa's forests to be completely destroyed, but the process has started. In most of Eastern and Southern Africa, as well as in the West African coastal countries, the process is far advanced.

2.9 Degradation and destruction of forests have a severe impact on wildlife habitat and biodiversity, with potentially irreversible losses of animal and plant life. The World Conservation Union (IUCN) and the World Resources Institute (WRI) estimate that 64 percent of original wildlife habitat in Sub-Saharan Africa has already been lost (Table 20). This is directly due to deforestation, conversion of wildlands to agricultural uses and other human activity. Uncontrolled harvesting, poaching and illegal trade also take a heavy toll on many species. Degradation of tropical moist forests has a particularly negative impact on biodiversity by destroying plant and animal life which may exist nowhere else in the world.

WRI has compiled estimates of the number of threatened species in Africa (WRI, 1992, pp. 304-309). Examples include the following:

- 18 of the 226 known species of mammals in Côte d'Ivoire are threatened with extinction, and 70 of the 3,660 known plant species are rare and threatened;
- Zaïre has the largest number of known species of mammals in Africa, and 22 of these 409 are threatened;
- 53 of the 105 known mammal species and 28 of the 250 known species of birds in Madagascar are threatened;
- in Chad, 18 of the 131 known species of mammals are threatened;
- in Kenya, 15 of the 314 known mammal species are threatened, and 144 of the 6,500 known species of plants are rare and threatened; and
- 1,145 of South Africa's roughly 23,000 plant species are listed as rare and threatened.

2.10 As forests and woodlands are destroyed, people must walk further and/or pay more for fuelwood, construction materials and other essential forest products. Woodfuels are the staple source of household energy in Africa, with 90 percent of all households using them for cooking — the main end-use of energy in Sub-Saharan Africa.⁵ Various agro-processing and rural artisanal and semi-industrial activities also use woodfuels (e.g., fish smoking, shea nut processing, tobacco drying, distilleries, pottery making, smithies, brick making). Fuelwood deficits are severe in the Sahel, in the savanna regions of West, Central and East Africa and in the arid areas of southeastern and southwestern Africa (Table 19). They impose particular hardships on women who are usually responsible for household fuel provision. As fuelwood becomes scarce, women (and children) have to spend more time collecting it from more distant sources and eventually begin to substitute crop residues and manure which would otherwise be used to maintain soil fertility.⁶

⁴ FAO/UNEP estimates for the late 1970s indicated that of West Africa's undisturbed, productive closed forests, almost 8 percent were logged annually, compared with only about 1.6 percent in East Africa and 0.4 percent in Central Africa (FAO and UNEP, 1981).

⁵ UNDP/World Bank, *African Development Indicators* (1992), Tables 14-8 through 14-14, provides country-specific data on energy consumption, including consumption of fuelwood.

⁶ The fuelwood problem and its impacts on rural households, family welfare, women's time and women's production activities have been investigated by many researchers; a number of such studies are listed in the bibliography.

2.11 The loss of future wood for the forest industry will be another important cost of continuing deforestation. In the period 1985-87, the six largest African timber exporters (Cameroon, Congo, Côte d'Ivoire, Gabon, Ghana and Liberia) exported US\$500-600 million worth of timber annually. Without significant afforestation, the potential for future export earnings will be lost as forests disappear.

2.12 Forests also provide a wide variety of non-wood products for local populations. Many are utilized particularly by women to meet subsistence needs or to generate cash income, and various wild plant and animal food sources are especially important in times of stress (FAO, 1989; 1990). A recent FAO publication lists 94 different forest and farm tree foods as being commonly used in West Africa (FAO, 1990a, pp. 102-103); 30 forest species are listed as being commonly used for fodder (*ibid.*, p. 113). Women often possess much specialized knowledge in this regard (Molnar and Schreiber, 1989); in Sierra Leone, women listed 31 different products they gather from bushes and trees near their villages (Hoskins, 1989, p. 43). Traditional medicine throughout Sub-Saharan Africa is highly dependent on a variety of forest plants.⁷ As forest are degraded and destroyed, these resources are no longer available and/or accessible to the local populations.

**Non-Wood Forest Products Gathered by Women
in the Arid Region of Brakna, Mauritania**

Foods & fodder: gums, fruits, leaves and grasses, chemicals from plants for preserving butter, *couscous* seasonings, a wild grain (*azr*) used as animal feed;
Medicines, cosmetics, dyes, etc.: medicinal plants, henna and pods for cosmetic purposes, incense plants;
Utensils, handicrafts, etc.: fronds, grasses, dyes, leather tannins, floor mats (Smale, 1985).

2.13 Deforestation also has a particularly severe impact on forest dwellers, such as the pygmies, threatening not merely their traditional lifestyles, but their very survival (Bailey, Bahuchet and Hewlett, 1992; Dyson, 1992; Peterson, 1992; Winterbottom, 1992).

(ii) Soil Degradation and Erosion

2.14 Much of Sub-Saharan Africa is highly vulnerable to soil degradation and erosion – because of factors such as soil characteristics, intense soil drying in the dry seasons, heavily erosive seasonal rainfall in many areas, wind erosion in drier areas, and low-resource farming with inadequate soil conservation measures. The United Nations Environment Programme estimates that more than 80 percent of Sub-Saharan Africa's productive drylands and rangelands, some 660 million ha, are affected by "desertification" – the process of sustained deterioration of the biological productivity of land (Table 23).⁸ Most of this is in the West African Sahelo-Sudanian Zone, in Sudan, Ethiopia, Somalia and Kenya, as well as in southern Africa, but parts of many other countries (such as the northern areas of many West African coastal countries) are also affected. The Soil Reference and Information Centre in Wageningen, Netherlands, has recently published more

⁷ The Inter-African Committee on Medicinal Plants and African Tropical Medicine and the Scientific, Technical and Research Commission of the OAU have published a pharmacopeia of African medicinal plants of proven efficacy, *African Pharmacopeia* (1985), and several African countries have established research institutes focussing on traditional medicine and the sources and effects of the active ingredients in medicines administered by traditional healers (DeJong, 1991).

⁸ The term "desertification" is often used without precision: it denotes a process of gradual loss of soil fertility and the consequent loss of the ability of soils to produce significant vegetative matter – trees, pasture or crops. Desertification is manifested in such phenomena as soil erosion, soil structure deterioration, compaction, reduction in organic matter and nutrient content, salinization, etc. "Land degradation" is a more appropriate term, with less alarmist connotations, and is increasingly gaining currency.

conservative estimates of the extent and severity of soil degradation in Africa. Its data indicate that about 321 million ha (14.4 percent of the total vegetated land surface) are moderately, severely or extremely degraded and an additional 174 million ha (7.8 percent of the vegetated area) are lightly degraded (Oldeman *et al.*, 1990).

2.15 Sizeable areas used for cropping in low-rainfall regions are subject to soil degradation and soil fertility loss. Topsoil losses even on gently sloping cropland have been reported to range from 25 to 250 tons per hectare annually from Niger to Madagascar and from Ethiopia to Zimbabwe (Table 22).

These rates are equivalent to losses of between 2 mm and 2 cm of topsoil annually.⁹ The agronomic relevance of such data is difficult to assess, of course, without information on new soil formation and total topsoil remaining:¹⁰ topsoil depth should be about 15 cm to provide an adequate root zone for annual crops (but optimal rooting depth differs among crops). Nevertheless, given the poor fertility characteristics of most African soils and the prevailing low-input farming practices, topsoil losses in the middle and upper ranges of the magnitudes reported will cause rapid productivity declines.

2.16 Soil erosion is usually accompanied by other aspects of soil degradation, such as deteriorating soil structure, reduced moisture retention capacity, soil nutrient depletion, and reduction in soil fauna and flora. A major study undertaken in the late 1970s estimated that, with unchecked soil degradation and erosion and no change in farming technology, the productivity of land in Africa would decline at an average rate of 1 percent per annum between 1975 and 2000 (Higgins *et al.*, 1982, pp. 23-25). In Zimbabwe, nitrogen and phosphorus losses attributable to soil erosion on arable land were estimated to be about three times the amount of fertilizer applied in the 1984/85 crop year; fully compensating for this nutrient loss through the application of chemical fertilizers would have cost about US\$ 1.5 billion – or US\$35 per hectare of arable land (FAO, 1990b).

Despite their pervasiveness, the extent and impact of the degradation, erosion and desertification of Africa's soils are not easy to assess. Reliable data on which to base national, regional and continental estimates are scarce. Soil erosion rates are difficult to calculate, and published data on degradation and erosion are highly location-specific and often of doubtful reliability, due to poor measurement techniques. They are also subject to considerable misinterpretation, especially when field data are extrapolated to develop aggregate estimates for entire watersheds, regions or countries. Moreover, most research on the relationship between soil degradation and erosion and soil productivity has been carried out in temperate zones (notably the United States), but there are vast differences in this relationship throughout the world as also in the resilience of land systems and the rate of new soil formation (Seckler, 1987; Stocking, 1987).

The Extent and Economic Cost of Soil Erosion in Mali

A recent study estimated soil erosion on cultivated land in Mali to range from a low of 1 t/ha/year in the arid Sahelian north to a high of 31 t/ha/year in parts of the more densely settled and intensively cultivated Sudanian south of the country. Given the enormous difficulties involved in quantifying the effect of soil degradation and soil loss on farm productivity, the researchers had to work with a range of values for the critical parameters that define this link. The associated crop yield reductions were estimated to range between 2 and 10 percent per year for the country as a whole. The present value (using conservative parameters of a 10-year time horizon and a 10 percent discount rate) of current and future net farm income foregone as a result of one year's soil loss was estimated to fall between 4 and 16 percent of agricultural GDP (Bishop and Allen, 1989).

⁹ There is location-specific evidence that erosion is accelerating. A study of Tanzania's Shinyanga region, utilizing the fact that trees and bushes can be dated to determine changes in ground surface height over time, found that soil erosion during the first 60 years of the current century averaged about 1.4 t/ha/year; 20-30 years ago, it was 10.5 t/ha/year; and during the past two decades it has averaged 22.4 t/ha/year (Stocking, 1987, pp. 56-57).

¹⁰ The natural rate of soil formation on non-agricultural land in temperate climates is about 0.8 mm per annum; it may be three times this much in the humid tropics (Seckler, 1987, p. 91). These rates are likely to be higher on well managed and lower on poorly managed farm land.

(iii) Rangeland Degradation and Desertification

2.17 About 25 million of the world's estimated 40 million nomadic and transhumant pastoralists live in Africa (Bass, 1990). Between 1963 and 1983, according to FAO estimates, the number of cattle increased by 74 percent in Sudano-Sahelian Africa, by 65 percent in humid and sub-humid West Africa, and by 61 percent in southern Africa (FAO, 1986). At the same time, the extent and quality of the rangeland declined. Cultivators moved into the best grazing areas and converted them to crop land; the traditional use rights of pastoralists, and particularly of transhumant herders, were ignored or overridden, and their herds were increasingly forced to more marginal land which is rapidly degraded by overgrazing. The increasing cultivation of valley bottom lands has further compounded the problem:¹¹ it restricts pastoralists' ability to move their herds there and to use these lands as migration routes during the dry season, thus forcing them to remain on degrading rangelands and around permanent waterpoints.

2.18 The problem has not simply been one of too many animals relative to the available grazing areas. Prolonged periods of below-normal rainfall and repeated severe droughts have accelerated the degradation of rangelands, and past efforts to address the problem of water supplies for pastoralists have often compounded, rather than ameliorated, the problems. Deep wells have been sunk to ensure water supplies during the dry season, but with free access to these wells, the number of animals congregating around them far exceeds the carrying capacity of the surrounding rangeland, causing rapid deterioration. Desertification has tended to spread outward from these areas of excessive and prolonged animal concentration.

(iv) Water Resource Depletion and Degradation

2.19 Rivers, streams, lakes, swamps and coastal waters are important resources that need to be protected and prudently utilized. They provide critical economic goods and services and perform vital ecological functions. These water resources are seriously affected by sedimentation, siltation, agro-chemical run-off, industrial pollution, etc.¹² Such problems are reported as becoming increasingly serious in many parts of Sub-Saharan Africa, although quantitative information is particularly poor in this respect. The causes include soil erosion, deforestation, destruction of protective vegetative strips alongside water bodies, indiscriminate drainage, encroachment for farming, poorly conceived irrigation development, lack of environmental regulations and enforcement on industrial activities, etc. Groundwater resources have also come under pressure, especially in the arid and semi-arid regions. Deforestation, soil degradation and erosion, and poor on-farm soil and water management practices all increase surface runoff (causing erosion) and reduce the amount of rainfall that infiltrates the soil and eventually percolates into groundwater aquifers. Prolonged periods of below-average rainfall and unusually frequent and severe droughts have, of course, greatly exacerbated this problem (Table 21).

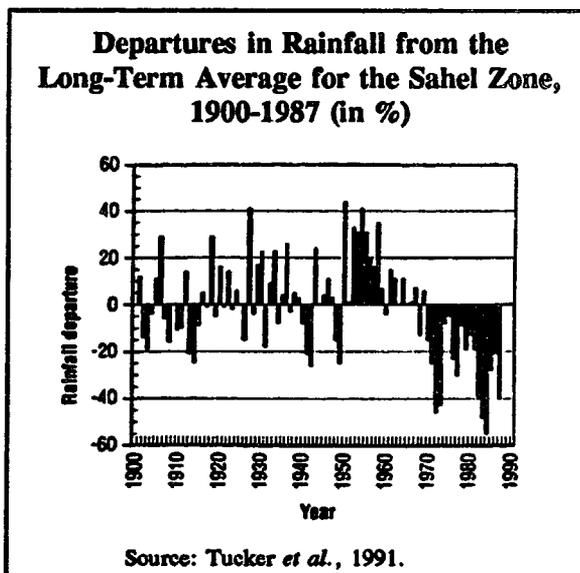

¹¹ Much soil eroded from uplands and slopes is deposited in the bottomlands along river courses. But these deposits are deficient in organic material and poorly structured, require good tillage and are too heavy for hoe cultivation or traditional ploughs. Access to more efficient agricultural technology (for land preparation, drainage to prevent waterlogging, etc.) has made it increasingly possible for land-hungry farmers to extend cultivation into these areas.

¹² Some water development projects have also led to problems. Major irrigation and hydropower developments have had adverse consequences for the flora and fauna of the floodplain, the carrying capacity of the floodplain grasslands, and the productivity and sustainability of farming based on traditional recession irrigation. Significant health problems have also been experienced with the spread of water-borne and water-related diseases.

2.20 Drinking water for human populations in rural areas is the most pressing concern, but water scarcity is also a severe constraint on livestock and home garden production in many parts of arid and semi-arid Africa and even in many sub-humid regions. During the dry season, rivers, streams and springs in many areas of Sub-Saharan Africa run dry, and women often have to go very far indeed to obtain meager quantities of water, often of very poor quality, for their families. As groundwater tables recede due to reduced rainfall and reduced rain infiltration into the soil and into subsurface aquifers, wells dry up and must be dug deeper or abandoned entirely.

(v) *Environmental Degradation and Climatic Change*

2.21 The consequences of environmental degradation are profound. Most alarming is the possible negative impact on rainfall, although direct causality is difficult to establish. The entire Sahel region has been the object of extensive meteorological monitoring and research; it suggests increasing aridity during the past two decades. The graph showing rainfall deviation from the 1900-1987 average is telling: it shows that the Sahel has always experienced wide variations in annual rainfall, but also that rainfall has been consistently and significantly below the long-term average every year since 1970 (Tucker *et al.*, 1991, based on Nicholson, 1989).¹³ There have also been significant declines in average rainfall in the coastal countries along the Gulf of Guinea and in eastern Africa.¹⁴

2.22 Climatologists' hypotheses to explain rainfall decline in the continent's drier regions include long-term climatic cycles and changes in ocean surface temperatures and in wind patterns over Africa brought on by changes in global atmospheric temperatures. None of the various hypotheses have been proven as yet, and the causes of Sahelian drought remain poorly understood. A broad consensus is emerging, however, that the causes of Sahelian drought are related to large-scale patterns of atmospheric circulation – specifically the reduced northward extension over Africa of the Inter-Tropical Convergence Zone (ITCZ), the band of wet weather that surrounds the earth where the trade

¹³ Satellite imagery has provided some interesting information recently, allowing scientists to determine the latitudinal movement of the southern edges of the Sahara (and of the other North African deserts contiguous with it) running across the continent from southern Mauritania to mid-Sudan. These data are available only since 1980, so that longer-term trends cannot be inferred from them. The Sahara expanded southward in the first four years for which these data are available (1980 to 1984) when there was a serious drought. As a result, the Sahara was about 1.3 million km² (or 15 percent) larger in 1984, when the drought was most severe, than in 1980. Although rainfall ever since 1984 has been significantly below the mean for 1900-1987, it has not again been as low as in 1984. The Sahara has therefore receded in size from its 1984 peak, but not back to what it covered in 1980 (Tucker *et al.*, 1991).

¹⁴ In Côte d'Ivoire, where deforestation has been the most rapid in Sub-Saharan Africa (Table 18), there has been a significant decline in mean annual rainfall at all monitoring stations during the 1970s and 1980s; the dry savanna has expanded southward from the northern part of the country through its middle toward the Atlantic coast (World Bank, 1989a). Annual rainfall in Senegal has decreased by 2.2 percent per annum over the past two decades, and there has been a sharp decrease in rainfall in northern Nigeria and Cameroon (Lele, 1989c; Lele and Stone, 1989). Statistics on mean rainfall throughout Ethiopia also show a precipitous decline during the same period (World Bank, 1987a).

winds from the southern and northern hemispheres converge (Odhiambo, 1991, p. 79). These ITCZ extensions, in turn, are affected by cyclical changes in ocean surface temperatures.

2.23 There also is increasing agreement that land surface changes -- which include changes in albedo, evapotranspiration, soil moisture, surface temperature and roughness, and the amount of dust generation -- can prolong and intensify Sahelian drought by reinforcing the atmospheric conditions which initially reduce rainfall (Nicholson, 1989, pp. 53-54). Evidence is accumulating which strongly suggests that the widespread and severe changes in land surface characteristics in West and Central Africa caused by human activity have disrupted the normal cycle of the ITCZ extension over Sahelian Africa, causing the prolonged drought. Changes in the land surface are partly caused by reduced rainfall itself, but human activity, notably deforestation and removal of vegetative cover on range and crop land, has a considerable impact. If the massive generation of smoke and atmospheric gases caused by biomass burning is considered, as it should, as an additional change in "surface" conditions over much of Western Africa, it is difficult to dismiss the conclusion that growing human populations have an impact on climatic change. Indeed, the effect of biomass burning of the enormous scale represented by African forest and grassland fires on the behavior and property of clouds is of increasing concern.¹⁵

2.24 Tropical forests are extremely important for recycling water between the Earth's surface and the atmosphere, and their disappearance has potentially serious consequences for regional and global climate. They are highly efficient in returning rainwater back to the atmosphere in the form of water vapor which forms new clouds and leads to subsequent rainfall. Rainforest regions thus store enormous quantities of water not only on the soil and biomass, but also in the atmosphere above them. When tropical forests disappear, water runs off quickly and much of it flows into the sea. This not only affects local and regional hydrological cycles, but also has potentially serious effects on climate. An important mechanism for the redistribution of heat is the atmosphere's ability to store energy in the form of water vapor and to release this energy again when vapor condenses into cloud droplets. If less water is available for this process, heat absorbed at the ground has to be moved away by other means such as radiation and dry convection, leading to higher surface temperatures and to changes in the vertical distribution of heat (Andreae and Goldammer, 1992, p. 88).

2.25 Deforestation is a major cause of the rapid increase in the accumulation of carbon dioxide (CO₂) and nitrous oxide (N₂O), two of the heat-trapping "greenhouse gases", in the atmosphere that cause global warming (MacNeill *et al.*, 1991, pp. 11-13). Burning of forests and grasslands to clear them for farming or to stimulate grass growth and control pests and shrub growth creates enormous atmospheric pollution with both regional and global implications. Recent evidence suggests that burning of biomass (forests, grasslands, agricultural wastes, fuelwood, etc.) world-wide is responsible for about one third of global emissions of carbon aerosols into the atmosphere. Africa accounts for about 13 percent of global biomass burning annually (largely through slash-and-burn agriculture in both forest and savanna regions and annual grassland burning) and contributes more to greenhouse gas emissions from biomass burning than any other tropical region of the world (Andreae and

¹⁵ Cloud droplets form around aerosol particles, called cloud condensation nuclei (CCN). Biomass burning generates and releases into the atmosphere vast amounts of pyrogenic aerosol particles which are very effective as CCN. The more CCN in the atmosphere, the more droplets form, resulting in smaller droplet size with a given amount of available water. Clouds composed of smaller droplets are lighter in color, reflect more sunlight back into space, and are less likely to produce rain. Since clouds are a major regulatory and control mechanism for the Earth's heat balance, large-scale modifications in cloud properties have a strong impact on global climate. The increasing abundance of CCN is, therefore, likely to have potentially critical impact on precipitation efficiency -- compounding the changes in hydrological cycles in the tropics caused by land surface changes such as deforestation (Andreae and Goldammer, 1992, pp. 87-88).

Goldammer, 1992). This relatively high contribution to atmospheric pollution is, of course, still far less than that caused by the burning of fossil fuels, most of which occurs in the industrialized countries of the northern hemisphere.

2.26 Acid deposition is higher in the Congo Basin and in Côte d'Ivoire than in the Amazon Region or in the eastern United States and is largely caused by direct emissions from biomass burning and by subsequent photochemical reactions in the resulting smoke and gas plumes. High levels of acid deposition have a negative effect on plant health and on fish and other aquatic organisms. Due to the longer average leaf life in the tropics, tropical forests are considerably more sensitive to foliar damage than temperate forests. Acid deposition also poses a serious risk to amphibians and insects that have aquatic life cycle stages and depend on rain water collected in plants and mosses and between dead leaves. This risk extends further to the many plants that depend on such insects for pollination. There is also an effect of soil degradation through progressive acidification and associated problems such as leaching of aluminum, manganese and other cations, interference with nitrogen cycling, and the disturbance of microbial processes in the soil (*ibid.*, pp. 88-89).

(vi) Environmental Degradation and Agricultural Stagnation

2.27 Soil degradation and erosion (excepting the often dramatic gully erosion that occurs where surface runoff is concentrated) are insidious processes, not readily apparent to farmers until the effects are severe and irreversible with the means traditionally available. They deplete the soil of nutrients, diminish its moisture retention capacity and reduce the depth of the rooting zone for annual crops. These effects exacerbate the impact of drought. Farmers and pastoralists in the semi-arid regions of Sub-Saharan Africa have always had to cope with drought, and they relied on effective adjustment mechanisms. But when drought is prolonged and extends over several successive years, as has been the case in the 1970s and early 1980s, the problems become serious.

2.28 The problems were compounded by the fact that the main traditional coping and adjustment mechanisms – shifting cultivation with long-duration fallows, and pastoralists' mobility – had become severely constrained. In the Sahel, for instance, rainfall during the 1950s and 1960s, when populations began to grow rapidly, was well above the long-term average almost every year. As a result, cultivation had been expanded into traditional rangelands, making both cultivators and pastoralists more vulnerable to drought. Range and pasture areas were reduced in size and the mobility of transhumant pastoralists was increasingly restricted. At the same time, a growing share of total crop land was in marginal areas, and changes in farming practices (e.g., shorter fallows, reduction of multi-variety seeding and intercropping, displacement of traditional drought-tolerant varieties) rendered farmers increasingly more vulnerable to climatic risk (as well as to plant pests and diseases).

2.29 As vegetative degradation and desertification proceed, the livestock carrying capacity of pastures and rangelands declines. Crop yields decline as the result of soil degradation and erosion on cropland. Available data on average cereal and root crop yields show decreases in many countries – despite significant investments in agriculture (Tables 10 and 12). Site-specific information confirms the problem in many countries.¹⁶ The data suggest that environmental degradation, accelerated by population pressures, is part of the cause of Sub-Saharan Africa's slow rate of agricultural and

¹⁶ See, for example, Barnes, 1990a and 1990b; Bishop and Allen, 1989; Elliot, 1986; Falloux and Mukendi, 1988; Gorse and Steeds, 1987; FAO/IBRD Cooperative Programme, 1991; Lal and Okigbo, 1990; Matlon, 1990; de Montalembert and Clement, 1983; Mortimore, 1989a and 1989b; Nelson, 1988; Stocking, 1987.

economic development -- through its negative impact on soil fertility, rainfall, water availability, fuelwood supply and other forest products. Exacerbating this are a frequently poor agricultural policy environment, low use of productivity-enhancing agricultural inputs, and the generally low productivity of rural labor -- attributable in large measure to low health and nutritional status and low educational attainment levels of the rural population.

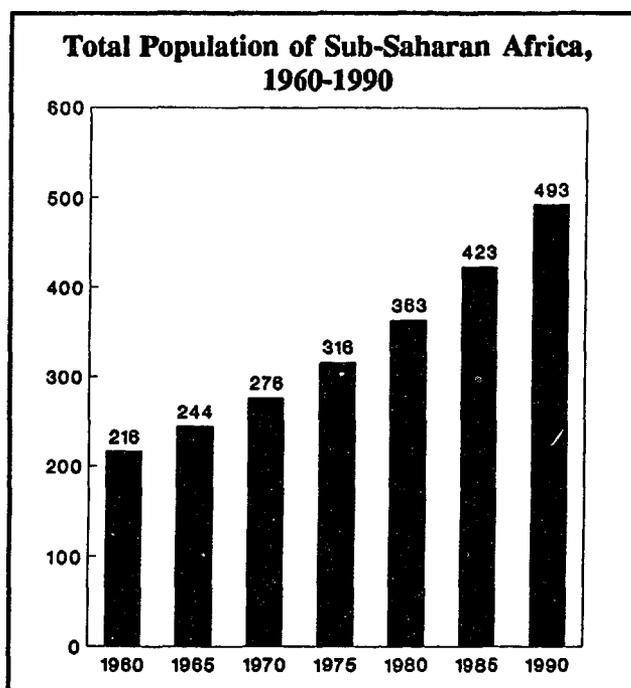

III. POPULATION GROWTH

A. The Lagging Demographic Transition

3.1 Sub-Saharan Africa lags behind other regions in its demographic transition. The total fertility rate (TFR) for SSA as a whole has remained virtually unchanged at about 6.5 to 6.6 for the past 25 years (Table 2). This is significantly higher than in other countries with similar levels of income, life expectancy, female education and contraceptive prevalence. In fact, fertility in a number of countries of Sub-Saharan Africa has risen (in large part due to significant success in treating diseases that cause infertility), while it has declined elsewhere.

3.2 Recent statistics, collected through nationally representative sample surveys carried out between 1986 and 1989 under the Demographic and Health Surveys (DHS) Program,¹ appear to signal, however, that several countries of continental SSA are at or near a critical demographic turning point (Table 8).² In Botswana, the TFR has fallen from 6.9 in the mid-1960s to 4.7 in 1989, and in Zimbabwe it has dropped from 8.0 to 5.3 over the same period. In Kenya, the TFR has declined from 8.2 in 1977/78 to 7.7 in 1984 and to 6.5 in 1989 (Kelley and Nobbe, 1990, p. 33.). Encouraging, too, are the data from Nigeria which indicate a TFR of 5.7 in 1990, compared with 6.9 in 1965. In Côte d'Ivoire, Ghana, Mozambique and Sudan, fertility also appears to have begun to decline (Table 2).³

3.3 Life expectancy in Sub-Saharan Africa has risen from an average of 43 years in 1965 to 51 years in 1990 (Table 1). In 18 countries, average life expectancy today is 53 years or more. Mainly due to the decline in mortality rates, population growth has accelerated from an average of 2.7 percent per annum for 1965-80 to about 3.1 percent per year at present (Table 2). And, given the age structure of SSA populations, the momentum for continued growth is already built in. Even if the TFR were to drop immediately to the replacement level of 2.2 births per woman, it would take almost a hundred years before the population would cease growing. By then it would be 80 to 100 percent larger than it is today.

¹ The DHS Program, a follow-up to the World Fertility Survey (WFS), is a nine-year program to assist developing countries in implementing 59 demographic and health surveys.

² The TFR has declined most dramatically in Mauritius, falling from 4.8 in the mid-1960s to 1.9 by 1990 (Table 2).

³ Detailed analysis of the DHS data is still in progress, and this study could therefore not yet draw fully on the information collected under the DHS Program.-- Note also that the data in Table 2, which represent the "best estimates" currently available in the World Bank's demographic statistical data base, do not yet in all cases fully reflect the most recent survey findings obtained under the DHS Program.

3.4 The high fertility rates, and the marriage, reproductive and contraceptive behavior patterns that underlie these, arise in part from the fact that most women live in rural areas, have little or no education, have few opportunities outside their traditional roles, and have limited legal rights. Childbearing enhances their status, and most women marry and begin having children early and continue to have them throughout their fecund years. But the comparative lack of urbanization and education does not explain everything: data available from the World Fertility Survey (WFS) for 1978-1982 indicate that both urban and rural, educated and uneducated women in Sub-Saharan Africa have and want more children than their counterparts elsewhere.⁴

The Bank's most recent projections assume that the TFR for Sub-Saharan Africa (including South Africa) will decline from 6.5% in 1985-90 to about 3.25% by 2030. This implies average annual population growth rates of just over 3% in the 1990s, 2.9% in the following decade and close to 2.6% in the decade thereafter. In this scenario, the SSA population would exceed 1 billion by the year 2012. By the turn of the present century, SSA would be second only to Asia in terms of total population. Aggregate population growth will remain above 2% p.a. at least until 2025, by which time the population of Sub-Saharan Africa, at 1,378 million, would be 2.6 times that of today. The net reproduction rate (NRR) will decline to 1 only by 2060. And Sub-Saharan Africa would reach a hypothetical stationary population of over 3.1 billion only some time after the year 2150 (Stephens *et al.*, 1991).

3.5 Women in Sub-Saharan Africa marry early: WFS data for the early 1980s show that, on average, 40 percent of all women aged 15-19 and 75 percent of those aged 20-24 were or already had been married (Cochrane and Farid, 1989). Early female marriage increases the number of fecund years a woman spends in union and therefore tends to exert upward pressure on the TFR. Even urban women in Sub-Saharan Africa marry earlier than rural women in North Africa and Asia (*ibid.*).

Data for the early 1980s indicate that the percentage of women who had ever used any contraceptive methods varied widely - from 2 percent in Mauritania to 74 percent in Côte d'Ivoire. The average for the ten SSA countries covered in the WFS was 26 percent, compared with 40 percent in North Africa and Asia and 62 percent in Latin America. The regional comparison was far worse when only "efficient" methods were considered: an average of 6 percent of SSA women had ever used these, compared with 32 to 50 percent in other regions.

3.6 Contraceptive use is far below that in other regions (Tables 5 and 6) and is associated primarily with the desire for child spacing, and only secondarily with the wish to limit family size (Table 6). Use of efficient contraceptive methods generally increases with urbanization.⁵ Low contraceptive use is due in part to poor knowledge.

Based on reported current users, contraceptive prevalence in SSA was very low indeed, of both efficient and inefficient methods. In six of the ten SSA countries surveyed, fewer than 1 percent of all women were current users of modern methods. The difference between "current use" and "ever used" was much greater in SSA than elsewhere, probably reflecting the much greater use of contraceptive practices for birth spacing in SSA (Cochrane and Farid, 1989).

There are wide differences among countries, but on average, only about half of all women in Sub-Saharan Africa had, by the early 1980s, heard of a way (either efficient or inefficient) to prevent pregnancy; this compared with rates of 85-95 percent

⁴ Under the WFS, national surveys were undertaken in the late 1970s and early 1980s. Using these data, Cochrane and Farid (1989) carried out a comparative analysis to ascertain similarities and differences in fertility and underlying causal factors between Sub-Saharan Africa and other regions; WFS data were available for ten SSA countries at the time they undertook their study.

⁵ Interestingly, when efficient and inefficient methods were considered together, urban use was higher than rural use in only three of the ten countries for which WFS data were available (Lesotho, Nigeria, Sudan). Traditional practices of fertility control, such as breastfeeding, might have been abandoned in the course of modernization, while modern methods were not yet adopted widely enough to offset this. This explanation is frequently given for the small differentials in fertility across socio-economic groups, but the available data on breastfeeding practices in Sub-Saharan Africa do not support this conjecture. Breastfeeding does not decline rapidly with increasing education (Cochrane and Farid, 1989).

in other regions (Cochrane and Farid, 1989). By the late 1980s, the DHS surveys showed measurable increases in the percentage of women who had knowledge of modern contraceptive methods: in 10 of the 12 SSA countries surveyed and for which data are available so far, between 64 and 98 percent of currently married women aged 15-49 knew of at least one modern contraceptive method (the exceptions were Mali and Nigeria, with only 29 percent and 41 percent, respectively). The DHS data on contraceptive prevalence rates (CPRs) indicate, however, the difficult task ahead: only between 1 and 6 percent of these married women were currently using a modern contraceptive method, and the percentage of married women using any contraceptive method ranged only between 3 and 13 percent. The exceptions, with significantly higher CPRs, are Botswana, Kenya and Zimbabwe (Table 8).

3.7 Among all groups of women, desired fertility is far higher in Sub-Saharan Africa than elsewhere. However, the WFS data analyzed by Cochrane and Farid also showed that: (a) younger women desire fewer children than do older women; (b) urban women want fewer children than do rural women (however, urban residence has not yet become a strong fertility depressant -- the rural-urban differentials being smaller in Sub-Saharan Africa than in other regions); and (c) educated women want far fewer children than do uneducated ones.

3.8 In Sub-Saharan Africa, as elsewhere, women's education affects fertility preferences, use of modern contraceptive methods, and fertility. Cochrane and Farid found that:

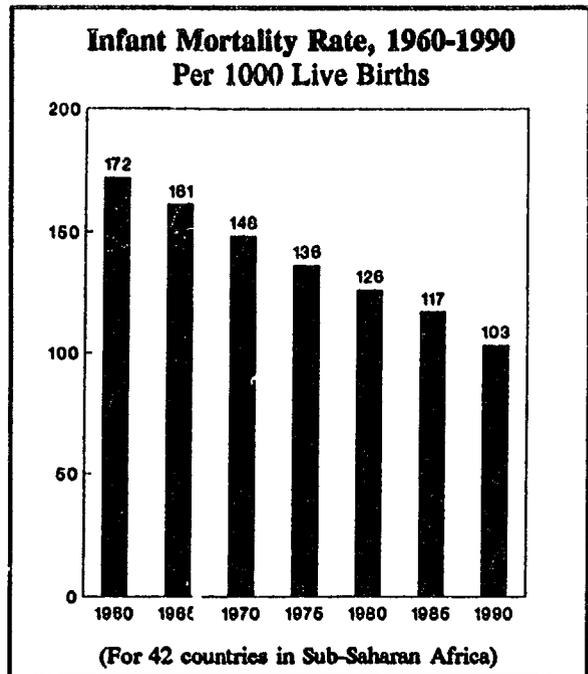

- there are considerable differences in desired family size among countries (see also Table 8), but with increasing maternal education there is both a decline and a clear convergence across countries;
- current use of any contraceptive method was only 4 percent among the least educated (compared with 19 to 34 percent in other regions of the developing world), but 19 percent among the most educated (compared with 43 to 56 percent in the other regions);
- although current use of contraceptive practices among the most educated women in Sub-Saharan Africa was only about the same as among the least educated in North Africa and well below the least educated in Asia and Latin America, even this comparatively low rate was sufficient to lower the TFR of women with 7 years or more of schooling to about 5; and
- fertility rises with a few years of primary schooling, but then declines (as elsewhere); but the effect of maternal education on fertility has been less pronounced -- to date -- in Sub-Saharan Africa than elsewhere.

3.9 The very high levels of infant and child mortality (Table 3) prevent achieving desired, or target, fertility levels -- and this helps explain the low CPRs (Tables 5 and 6). Contraceptive use increases as the number of living children increases. Although infant and child mortality have declined over the past two decades (in some countries substantially), they remain much higher than in other regions (albeit with considerable differences among countries).⁶ Higher rates of child

⁶ Infant and child mortality are both higher in SSA than in other regions. The differential is higher in the case of child mortality, due to high mortality in the second and third years of life following weaning. Toddler and child mortality in SSA are two to three times greater in SSA than in Latin America and Asia. Toddler and child mortality at all levels of mother's education are higher than in other regions (Cochrane and Farid, 1989). See also Table 3.

survival reduce the need to replace children who have died or to have more children to insure against the possibility of future deaths. Infant mortality rates are well below the average for Sub-Saharan Africa in Botswana (37), Kenya (60), Zimbabwe (53) and Nigeria's Ondo state (56). The same is true for child mortality rates where the SSA average is 154: Botswana (53), Kenya (69), Zimbabwe (75) and Ondo state (108).⁷ In each of these cases, the TFR has begun to show a decline, signalling the onset of the demographic transition (Table 8).

3.10 Infant mortality is highest in rural areas, and children born to young mothers are at greater risk. Infant mortality is also higher for first-born children and those born seventh or later. Children's survival chances are greater if the interval from the previous pregnancy is longer (maternal attrition, lower risk of low-birth weight babies, maternal attention). Infant and child mortality decrease consistently with the mother's education. Urban-rural differences in infant and child mortality are significant and somewhat larger in Sub-Saharan Africa than in other regions.

3.11 Prolonged and near universal breastfeeding has been the main factor keeping fertility below a biological maximum in most SSA countries. Although the duration of breastfeeding is generally shorter in urban than in rural areas, it does not decline as rapidly with mother's educational levels as in other regions. The most educated women in Sub-Saharan Africa breastfeed considerably longer than those in Latin America and Asia. Breastfeeding has important positive effects on child health – and, indirectly, via reduced infant mortality, on fertility decisions and maternal fertility. It also affects birth spacing – and thereby maternal health, infant health, and fertility. In this respect, post-partem infecundity is far more important in Sub-Saharan Africa than elsewhere, accounting for 59 percent of the reduction in fertility from biological maximum. On average, fertility in SSA is only 67 percent of what it would be in the absence of breastfeeding (Cochrane and Farid, 1989).⁸

B. Fertility and Agriculture: Part of the Nexus?

3.12 Fertility is highest in rural areas – reflecting a variety of economic as well as socio-cultural factors (not necessarily unique to Africa) which affect fertility aspirations. Traditional lineage and kinship systems, gender roles and relations between generations contain strong pro-natalist forces, and in traditional communities women's fertility is a major determinant of their status. Extended families, where the costs of high fertility are widely shared and only partly internalized by

⁷ For Sub-Saharan Africa as whole, the infant mortality rate is estimated at 103 and the child mortality rate (for children under 5 years of age) at 154 (Table 3).

⁸ Nevertheless, fertility patterns do not seem to be fully explained by the proximate determinants of marriage, post-partem infecundity (breastfeeding) and contraceptive use. Abortion, sterility, sub-fecundity and/or spousal separation appear to suppress the "maximum" fertility below that observed in other regions. This suggests the need for more research on other determinants of fertility to understand current levels and probable future trends (Cochrane and Farid, 1989).

the couple that makes the fertility decision, tend to encourage high fertility. In most of rural Sub-Saharan Africa, agricultural labor is not readily available for hire. Labor must be mobilized essentially from within the "household" or through social, communal or kinship arrangements specific to the area and community. For men, polygamy/polygyny is one widely practiced way of securing additional labor -- of women and their children (but even women may welcome co-wives as co-workers to help share the burden).⁹

3.13 Women may recognize far more readily than men the costs of high fertility to their own and their children's health. This may be particularly prevalent in polygamous unions where each woman is responsible for her own children. The costs of children are lower to men than to women, yet the value of child labor may be higher to the mothers than to the fathers -- except in communities where fathers have and assert priority rights to their children's labor. For women, the labor of their own children is often the only means of securing adequate labor to cope with their many responsibilities.¹⁰ As water and fuel resources become more scarce and the time required to obtain them increases, the need increases for children to help with the mothers' increasing work load associated with these survival activities. Child labor is also increasingly needed to compensate for declining male labor in foodcrop production, particularly in poor families which cannot hire wage labor. This may contribute to the maintenance of high fertility rates.¹¹ In much of Sub-Saharan Africa, men and women cultivate different crops on separate plots, and women's farming systems depend very heavily on female and child labor. Most women marry at a very early age and usually considerably older men; this, coupled with the high rates of divorce/separation and the fact that in most African societies women can obtain access to critical assets (such as land) and public services only through male relatives, may increase their willingness to bear many children so as to have sons to turn to when husbands leave or die. The desired number of children is considerably higher among rural women in Sub-Saharan Africa than among their counterparts in any other region of the world. And in no other region of the world do women play as significant a role in agriculture as in Sub-Saharan Africa.

3.14 The characteristics of traditional land tenure systems may also bear upon fertility decisions -- but more research is needed to establish this link. Where access to land for farming is granted to all members of a community, this may be a disincentive to fertility control. Where the amount of land allocated is based on the ability to cultivate it, this ability -- under the low-resource farming conditions prevailing in most of Sub-Saharan Africa -- is primarily determined by the ability to mobilize labor. In most cases, this means family labor -- more specifically, female and child labor. Indeed, a number of field studies report this to be an important incentive to increase family size through such means as polygamy and/or pressure on women to have many children.

3.15 Among groups with matrilineal descent and inheritance traditions, further complications may arise because land use rights are not passed on from fathers to their children, but to uterine relatives (in most cases males). This weakens the link between land availability and land resource management on the one hand and demand for fewer children on the other. It also weakens men's

⁹ Polygamous men generally have more children than monogamous men -- while women in polygamous marriages tend to have fewer children than those in monogamous marriages (Bongaarts *et al.*, 1990, pp. 135-136).

¹⁰ In a number of communities, women try to ease their peak labor constraints by participating in various forms of kinship- or community-based work group and labor exchange arrangements.

¹¹ This is suggested, though not necessarily proven, by the statistical analysis summarized in the box on page 25.

incentives to invest in maintaining the fertility of the land they farm.¹² Fathers may see little point in preserving farm land in good condition beyond their own lifetime or in having few children so as to pass on a viable farm unit to each of them. Women, conversely, may face social pressure to bear many children so as to increase the number of future claimants to land resources who belong to their lineage.

3.16 The implication derived from the above is that most rural Africans attach high economic value to having large numbers of children. Larger families appear to fare better economically than small families. Children contribute labor in cropping, livestock tending, water and fuelwood fetching, and child rearing. The available evidence, although imperfect, suggests that high demand for children may be partly the result of the historic abundance of land and the shortage of labor, combined with high infant, child and overall mortality rates and high food insecurity. Maintaining high fertility is the rational response of people who seek to ensure adequate family labor and the survival of children to provide support to them in old age. For men in particular, polygyny makes good sense in this situation because it increases the supply of female and child labor and improves the prospects for security in old age. The widespread practice of payment of a bride price for a woman (instead of the woman's family providing a dowry) reflects this reality where women are wanted for their labor and their ability to bear many children. Early female marriage, common in Africa, also increases the prospects for multiple childbirths.

3.17 Various other trends also tend to keep the TFRs high. As forest resources, water availability and soil fertility decline, farmers and pastoralists obtain less product per hectare. The main resource available to them to increase production is family labor which permits increasing the extent of the land farmed. It also facilitates diversifying the sources of family income by taking up more seasonal or full-time off-farm employment. Hence, agricultural stagnation and environmental degradation, in resource-poor situations characteristic of most of Sub-Saharan Africa, provide an economic incentive -- and often a survival strategy -- to maintain large families. These factors also provide an incentive to keep children out of school to work on the parental farm or with the family's livestock, as well as to convert forests, woodlands and savannas into cropland.

3.18 This situation is exacerbated by the specific and important responsibilities placed on women in most farming systems of Sub-Saharan Africa. Women are often responsible for food cropping, and almost always for fuelwood and water provision (see Chapter V). As soil fertility declines and distances to fuelwood and water sources increase, many rural women are faced with the situation that the only resource that can be increased to meet the increasing need for labor is child labor. More labor substitutes for reduced soil fertility and compensates for the greater difficulty in obtaining fuel and water. This then completes a vicious circle in which population growth, combined with traditional farming practices, contributes to environmental degradation, in turn contributing to further agricultural stagnation and to the persistence of high rates of population growth.

3.19 These hypotheses are consistent with statistical tests (see the box on page 25) which show that, *ceteris paribus*, TFRs are highest in those SSA countries which have the most cultivated land per capita. Similarly, TFRs are highest in countries with the highest infant mortality rates and poorest food security, all other things being equal. This suggests that demand for children as well as TFRs will decline over time as population density on cultivated land increases, female school

¹² Among the matrilineal Akan in Ghana, it is frequently observed that a son employed in urban areas is extremely reluctant to have remittances he sends to his fathers invested in improving the father's farm ventures because these investments will, upon the father's death, benefit their maternal uncles or cousins, rather than themselves.

enrollment rates rise, infant mortality declines, food security improves and environmental resource degradation is minimized.

3.20 However, changes in these determinants of demand for children are coming about only slowly. The analysis of the available cross-country data suggests a considerable degree of inertia in fertility rates as well as the presence of many other factors that influence fertility rates out for which data are not available or simply cannot be generated. Cultural factors appear to be very important in this regard.¹³ They are likely to change only slowly, even though the factors which help shape culture are changing. Fertility rates will decline, therefore, even without an active population policy -- but only slowly, and only if food security and infant mortality improve and environmental degradation is arrested. But these changes are occurring too slowly to compensate for the enormous difference between the rates of growth of population and of agricultural production.

3.21 Nonetheless, rising population pressure on cultivated land, declining infant mortality rates and improvements in female education are stimulating demand for family planning services, and much of this demand remains, at present, unmet (Table 6).

¹³ Commenting on the findings obtained from the analysis of the WFS data collected in the late 1970s and early 1980s, one of the program leaders stated, in fact, that the onset of the demographic transition "appears to be determined more by ill-understood cultural factors than by any objectively ascertainable development indicators" (Gille, 1985, p. 279).

Statistical Analysis to Explain Inter-Country Variations in Total Fertility Rates (TFRs)

1. The available data were used to test several of the findings from the country-level analysis about the determinants of high TFRs in Sub-Saharan Africa. Data were available for 38 countries. The methodology is cross-sectional, looking at statistical relationships in the variation of variables across countries. (The data used and a discussion of the methodology are presented in the Annex.)

2. For the statistical test, TFRs are hypothesized to be related to the independent variables as follows: positively to infant mortality (the higher the expected loss of infants, the more births are desired to assure that there are some survivors); negatively to food security (the greater the food security, the lower the need for children to provide family labor for food production since sufficient other factors of production are available); negatively to female primary school enrollment (better educated women want fewer children); positively to cultivable land per person (the more cultivated land per person, the greater the need for family labor to help cultivate it); and positively to the rate of deforestation (the higher the rate of deforestation, the greater the need for child labor to help with wood gathering and water fetching).

3. This hypothesis is tested by means of a statistical regression in which the TFR is the dependent variable. The result is as follows:

<u>Independent Variables</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	6.5	4.2	1%
Female primary school enrollment rate	-0.005	0.9	37%
Hectares cultivated per person (a)	0.16	0.6	53%
Infant mortality rate	0.01	2.0	6%
Calorie supply as % of requirement	-0.02	1.2	25%
Rate of deforestation	0.29	2.4	2%

Adjusted R squared = 0.4

F-statistic = 5.5

(a) = converted to natural logarithm.

4. The coefficients are consistent with the hypothesis, but only infant mortality, the rate of deforestation and the constant term are statistically significant at or above the 90% level (i.e., with a 2-tail significance test of 10% or lower). The 2-tail significance test indicates the probability that the coefficient is actually zero. Hence, a 2-tail test of 2% for the rate of deforestation indicates a 2% probability that the coefficient is zero, or a 98% probability that it is not zero. The relatively poor fit of the equation and of some of the variables may be explained by the poor quality of the data, but there probably is also considerably more to explain the TFRs than is captured in the data used here. As a result, an expanded data set is being compiled to test the hypothesis, using pooled cross-country data and time series data.

5. The statistical results, combined with the site-specific evidence cited in the text, suggest that the TFR is lower as female primary school enrollment is higher (although the coefficient is not statistically significant). The greater the area cultivated per person, the higher the TFR (but again the coefficient is not statistically significant). The higher the infant mortality, the higher the TFR. The better the level of nutrition, the lower the TFR; better nutrition translates into better maternal and child health (and, hence, into lower infant and child mortality), but also improves the ability to feed one's family with the available factors of production, including household labor, and this in turn lowers the demand for child labor. A correlation between better nutrition and lower TFRs may also reflect the beginnings of the demographic transition -- as better-off people (with access to more food) reduce their family size. The highly significant positive association between the rate of deforestation and the TFR is noteworthy: this may reflect, as hypothesized, the greater demand for child labor as environments deteriorate (more labor required to obtain fuelwood and water and to produce sufficient food as the productivity of farm land deteriorates due to deforestation). Unfortunately, this type of analysis cannot establish causality, which may run in the opposite direction -- i.e., higher fertility leading to faster population growth and more rapid deforestation. Or there may be a mutually supportive synergy between these two variables.

6. Given the lack of statistical significance of three of the variables and the problem of direction of causality with deforestation, these statistical tests serve only to suggest the plausibility of the hypothesis. The tests do not prove or disprove it. The evidence cited in the text from various countries is more solid, but statistical verification of the hypothesis remains to be accomplished.

IV. THE NEXUS BETWEEN POPULATION GROWTH, AGRICULTURAL STAGNATION AND ENVIRONMENTAL DEGRADATION

A. The Main Linkages

4.1 The preceding chapter cited some evidence suggesting that stagnating agriculture and environmental degradation, combined with traditional land tenure systems and the traditional roles of rural women, may contribute to maintaining high fertility rates. These systems and practices appear to create a demand for child labor as a family survival strategy. The complexity of this analysis is created by the multiplicity of factors which affect the rate of population growth, environmental degradation and slow agricultural development in Sub-Saharan Africa. In addition, there are important variations across countries. This chapter pursues the analysis of synergetic links between rapid population growth, poor agricultural performance and environmental degradation. The role of women in rural production systems, a major link in the nexus, is discussed separately in Chapter V.

4.2 The complexity of these linkages and the ambiguity of the analysis result primarily from Ester Boserup's finding that agricultural intensification occurs as population density on agricultural land increases (Boserup, 1965). Others have published more recent material confirming the applicability of the "Boserup hypothesis" to many developing country situations, including in Sub-Saharan Africa.¹ It should not be surprising that this phenomenon has been observed so widely. Farmers are unlikely to have an incentive to intensify their agricultural production (i.e., to generate more output per unit land area) unless there is a constraint on land. If there is no land constraint, and land is free or very cheap, it makes sense from the farmer's perspective to extend the use of land and minimize the use of other inputs, including capital and labor. Shifting cultivation and pastoral livestock raising are perhaps the best illustrations of this situation. They have predominated in most of Sub-Saharan Africa.

Ukara Island, Lake Victoria (Tanzania): Agricultural Intensification under Population Pressure

An extreme example of agricultural intensification under population pressure is that of Ukara island in Lake Victoria. Faced with considerable population pressure and soils of inherently low fertility, the island's inhabitants, the Kara (or Wakara), had developed, prior to European contact, a highly refined intensive farming system which included erosion control, crop rotation with intercropping and green manuring with legumes, fodder cultivation, stabling of cattle and fertilizing (farm-yard manure, leaf manure, household ash) of fields. The tenure system was based on private property, with inheritance and sale of land. The system has, however, reached its limits. The island's population has numbered about 16,000 since the beginning of the century; population density is about 500 per km², and the average family holding amounts to 1 ha of arable land. There has been little, if any population growth, whereas there has been substantial population growth in the rest of the Lake area where shifting cultivation is still practiced. Excess population moves to the mainland, where labor-intensive techniques are quickly abandoned because the returns to labor are far higher with the extensive systems still possible on the mainland (Koeber, 1973; Ruthenberg, 1980, pp. 158-160).

4.3 Consistent with Boserup's findings, these traditional extensive farming and livestock systems change, even in traditional society, when populations become more dense. This can be seen in the Kenya highlands, Burundi, Rwanda, the Kivu Plateau in eastern Zaïre and in parts of Nigeria. In Rwanda in particular, intensive traditional agricultural systems exist, brought about by the scarcity of land relative to the population dependent on it. In most of Sub-Saharan Africa however, land has been abundant until recently, and in some countries it still is.

¹ See, for example, Binswanger and Pingali, 1984, 1988; Pingali, Bigot and Binswanger, 1987; Lele and Stone, 1989.

4.4 The hypothesis is that rapidly increasing population pressure has overwhelmed rural African traditions of farming, livestock raising, fuelwood provision, land allocation and utilization, and gender-specific responsibilities in household maintenance and rural production systems. Traditional crop production and animal husbandry methods, traditional land tenure systems and land use practices, traditional methods of obtaining woodfuels and building materials, and traditional responsibilities of women in rural production and household maintenance worked well and could evolve slowly when population densities were low and populations were growing slowly. The persistence of these traditional systems and practices, under stress from the high population growth rates in the past 20 to 30 years, has led to an accelerated degradation of natural resources. This in turn has contributed to agricultural stagnation since the 1960s. In summary, Africans have been unable to modify their traditional agricultural and renewable resource use practices quickly enough to respond to the pressure of a rapidly increasing population on the available resource base.

The Kofyar in Nigeria
Extensive Farming When the Land Frontier Opens

The Kofyar initially lived as subsistence farmers on the Jos Plateau in north-central Nigeria. As population density on the escarpment increased, they intensified their farming system, with increasing reliance on agro-forestry, terracing and manuring. When population growth on the Plateau out-iced the ability of their farming system to sustain the increased numbers, the Kofyar obtained permission from tribes in the Benue plains to clear low-land forests and farm on the newly cleared land. The migrants immediately abandoned the intensive farming techniques they had practiced on the Plateau and adopted instead an extensive forest-fallow farming system focused on cash cropping and market-oriented animal production. The subsistence farms on the Jos Plateau had averaged about 1.5 acres, while the new farms in the cleared forests averaged 7.5 acres (Stone, 1984).

4.5 The complexity is further increased by interaction with the economic policy environment characterizing many African countries since the mid 1960s. Agricultural price, trade, exchange rate and tax policies in many African countries have often combined to render agriculture unprofitable (World Bank, 1989d). The mechanisms for developing and transmitting improved agricultural technology are severely inadequate throughout Sub-Saharan Africa. And excessive government control of agricultural marketing and processing has either squeezed out the private sector on much of the continent, or forced it to operate in a clandestine manner. Yet public-sector marketing and processing enterprises have performed poorly. Farmers have not usually been permitted to associate freely in farmer-managed cooperatives, nor to freely market their products. Throughout Sub-Saharan Africa, this lack of empowerment of farmers has discouraged them from investing. To break out of the trap of rapid population growth, low agricultural growth, and environmental degradation, these policy constraints must be overcome. The World Bank's 1989 long-term perspective study on Sub-Saharan Africa suggested how this might be done (World Bank, 1989d). It is the thesis of this paper that measures will also be needed to overcome the constraints imposed by increasing population pressure on traditional cultivation, fuel provision and tenure systems, and by the roles traditionally assigned to women in rural societies. Appropriate policy reforms will make the more rapid evolution of these traditional systems easier.

B. Traditional Cultivation and Livestock Husbandry Methods

4.6 For centuries, shifting cultivation and transhumant pastoralism have been, under the prevailing agro-ecological conditions and factor endowments, appropriate systems for people throughout most of Sub-Saharan Africa to derive their livelihood, in a sustainable manner, from the natural resource endowment of their environment. The ecological and economic systems were in equilibrium. The key to maintaining this equilibrium was mobility: people shifted to a different location when soil fertility declined or forage was depleted, allowing the fertility of the land to be reconstituted through natural vegetative growth and decay. For field cropping, this typically involved

cultivation periods of two to four years, land then being left fallow for as long as 15 to 25 years. Transhumant herders' mobility generally involved a far greater geographic range, but a far shorter temporal cycle: they would move their herds on extended migratory patterns as dictated by the seasonal availability of water and forage and in most cases repeat the same cycle in one or sometimes two years.

4.7 These mobile systems of shifting and long-fallow cultivation and transhumance were suitable because of low population density, abundant land, limited capital and technology and frequently difficult agro-climatic conditions. As long as population growth was slow and land remained available, the additional people could be accommodated by gradually bringing more land into the farming cycle and establishing new settlements on previously uncropped land. Adjustments, including gradual intensification of farming practices, took place as and when they became necessary, but the pace of adjustment

required was slow because population growth was slow. The inter-cropping by Rwanda's farmers, for example, was an early traditional adaptation, because shifting cultivation was increasingly constrained by the relatively high population density.

4.8 In the absence of sufficiently rapid and widespread technological change, population growth has led to the expansion of the area under cultivation. This has involved mainly the conversion of large areas of forests, wetlands, river valley bottoms and grassland savanna to crop land. Since 1965, the area farmed has increased by over 21 million hectares (Table 16). Much of this has taken place on ecologically fragile and agriculturally marginal land which is not suitable for sustained farming and eventually abandoned in an advanced state of degradation. Forested land has declined by about 65 million ha since 1965 (Table 16). But land available to expand cultivation has become increasingly scarce in most regions of Sub-Saharan Africa, drastically narrowing the scope for further expansion. Over the past 25 years, crop acreage expanded by only 0.7 percent annually, and the population pressure on cropped land has increased sharply. On average, per capita arable land in Sub-Saharan Africa declined from 0.5 ha per person in 1965 to 0.4 ha/person in 1980 and to less than 0.3 ha/person in 1990 (Table 17).²

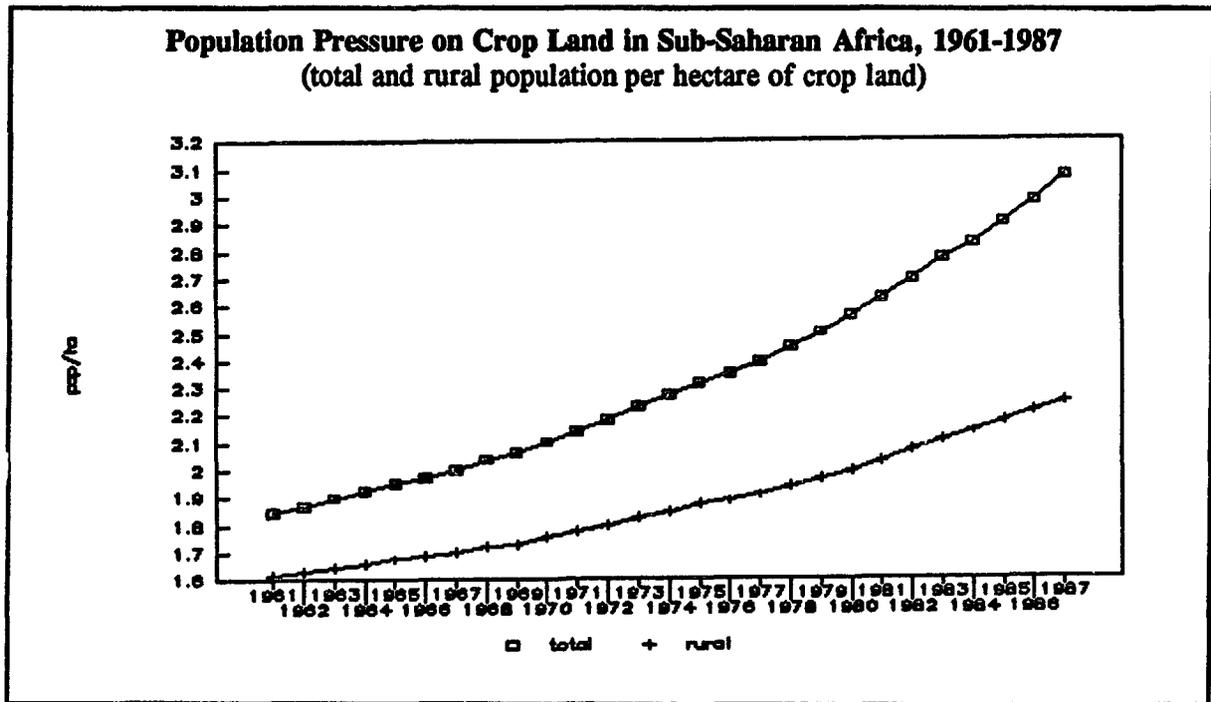

4.9 Due to the effect of agro-climatic and soil characteristics, the potential productive land endowment per capita in most of Sub-Saharan Africa is even poorer than these simple acreage statistics suggest. Niger, for example, is even more densely populated than India or Bangladesh if account is taken of the extremely poor quality of its agricultural resource endowment. Nigeria and Senegal are more densely populated than the Philippines. And Mali, Burkina Faso and The Gambia are twice as densely settled as Indonesia (Binswanger and Pingali, 1986; Matlon, 1990).

Land Requirements for *Chitemene* Cultivation

The suitability of land for *chitemene* cultivation in Zambia depends, *inter alia*, on the density of woody vegetation available for cutting and on the land's regeneration capability. A person completely dependent on *chitemene* requires one hectare under cultivation each year for survival (Stalen, 1983, pp. 31-32; Vadeld, 1983, pp. 98-100). If 50 percent of the land in an area is suitable for *chitemene* and the regeneration cycle is 25 years, the aggregate land requirement for long-term ecological sustainability of the system is 50 ha per person. In a village of 200 people, requiring a total area of 100 km² to sustain *chitemene* farming, individual fields would therefore be as far as 5.1 km away from the village -- assuming the village land forms a circle and the village is located in the center of this circle.

This simple arithmetic also shows that traditional farming and land use practices, combined with limitations on the time people can afford to spend walking to and from their fields each day, limits the size of farm settlements. Some people eventually migrate to establish satellite villages in virgin forest land once the situation in their home village becomes too difficult.

² For comparison, crop acreage in China declined from 0.6 ha/person in 1965 to 0.4 ha/person in 1987. In India, it declined from 0.3 ha/person in 1965 to 0.2 ha/person in 1987 (Table 17).

4.10 There is considerable diversity among countries, but everywhere fallow periods are becoming shorter as populations increase and the land frontier recedes. In many areas of countries, from Mauritania to Lesotho, fallow periods are no longer sufficient to restore soil fertility. Increasingly, farmers are compelled to remain on the same parcel of land, due to the unavailability of unoccupied land – yet they change their traditional farming methods only very slowly.

4.11 These people are faced with a critical dilemma: a central element of their traditional farming system -- the ability to shift around on the land -- is being eliminated by population pressure, yet they continue to use the other elements of their traditional production systems. Where fallow periods are too short, or non-existent, and where traditional cultivation techniques continue to be used, soil fertility deteriorates and soils are not conserved. Wind and water erosion, soil nutrient depletion, acidity, and deteriorating soil structure become common and increasingly severe. As a result, crop yields decline, forcing farmers to expand production along the already receding land frontier. This expansion occurs firstly within the vicinity of their settlements -- on more steeply sloping land and in nearby forest, wetland and range areas. As this option becomes increasingly limited, people migrate to establish new farms, often in semi-arid areas and in tropical forests where soil and climatic conditions are poorly suited to the cultivation of annual crops and yields are therefore low. The migrants bring with them the knowledge of those techniques they practiced in the areas they abandoned, and these are often detrimental to their new environment. Although they soon begin to experiment with simple modifications in farming techniques, this indigenous adjustment has been too slow in the 1970s and 1980s to keep pace with the rapid rate of population growth.

4.12 Good pasture land is diminishing as the most productive tracts are converted to cultivation. The mobility of pastoralists' herds is further reduced as settlers increasingly cultivate bottom lands previously available to herders during their dry season migration. The concentration of increasing numbers of livestock on smaller areas destroys pasture vegetation, further reducing their carrying capacity and contributing to range degradation and eventual desertification (Gorse and Steeds, 1987; Falloux and Mukendi, 1988; Nelson, 1988).

4.13 Diminishing forest and woodland resources provide less fuelwood and fewer other forest products, many of which are of considerable importance for rural livelihood and survival systems. Similarly, surface and groundwater resources are increasingly affected by the drastic alterations in land uses and vegetative cover. The effects of the worsening fuelwood and water scarcity are most directly felt by some of the most vulnerable: women and children. More time and effort are required to obtain these vital commodities. Or people must manage with less of them. One consequence of reduced woodfuel availability is the increasing use of dung and crop by-products as fuels (see para. 4.40). This reduces their availability as farming system inputs to maintain soil fertility. Similar effects result from diminished availability of, and access to, water for household and home garden use: health and sanitation standards deteriorate, and home garden productivity declines.

4.14 These problems are gravest in parts of the Sahel and of mountainous East Africa and in the dry belt stretching from the coast of Angola through southern Mozambique. The crisis is most acute in countries that already have little arable land per capita and high population growth rates, such as Burundi, Kenya, Rwanda, most Sahelian countries, Nigeria, and Togo. There, soil degradation and loss of vegetative cover are advanced, and agricultural productivity is stagnating or declining. In parts of these countries, population pressure is causing farmers to intensify their production methods, but for the most part this is occurring much too slowly.³

4.15 There are other countries where it appears that land is more abundant in relation to their current population. These countries lie in Central Africa, humid West Africa and Southern Africa. However, much of the potentially arable land in Central and humid West Africa is under tropical forest. To preserve biodiversity, maintain rainfall, and preserve the humid climate on which its tropical agriculture is based, much of this area should not be cultivated. Instead, the humid forests need to be preserved. This land has not been cultivated so far because it is poorly suited to cultivation (except possibly of certain tree crops). Soils in Africa's rain forest zones are typically low in nutrients and of high acidity. Even in these more land-abundant countries, the problem which is the focus of this paper can already be observed. An expanding population depending on agriculture and livestock is moving into the tropical forest areas, extending crop production and grazing into areas that are agro-ecologically unsuited to these forms of land use.

4.16 No analysis is available that quantifies the impact of environmental degradation caused by more people practicing traditional shifting cultivation and transhumant and pastoral livestock raising. It has therefore not been possible to separate the contribution of this phenomenon to poor agricultural performance in Sub-Saharan Africa from that of the policy problems identified in para. 4.5. There appears to be little doubt, however, that these policy deficiencies have slowed down the evolution of traditional systems into systems more sustainable with higher population density. (A statistical test of this hypothesis is summarized in the box on pages 41-42.)

C. Land and Tree Tenure Systems and the Nexus

4.17 Critics of traditional tenure systems in Sub-Saharan Africa argue that they constrain agricultural productivity and cause environmental degradation -- because land resources are not privately owned, but are either common property of a community, clan or ethnic group, or open-access resources owned by no-one at all. They further argue that users of such resources have no incentive to limit their consumption thereof because they cannot be certain that other users will similarly limit theirs. Lacking secure property rights, individuals are dissuaded from adopting long-

³ Olson (1990) provides an interesting analysis for Rwanda.

term conservation, investment and production strategies. There are two possible solutions, it is argued, to this problem: (a) establishing firm rules, with enforceable sanctions, which limit individual use of the resource for the common good, or (b) individualization/privatization of resource ownership and tenure, and registration of individual titles. In the critics' view, rapidly rising population pressure makes effective common ownership regulation increasingly more difficult. Based on the "tragedy of the commons" argument, they urge that land be placed in individual private ownership.

4.18 Opponents of tenure individualization focus on its alleged negative impact on land distribution and social equity. Evaluations of tenure reform in Kenya and Botswana are cited as showing that individualization of land tenure has led to land grabbing, concentration of land ownership, *de facto* expropriation of women, landlessness and increasing marginalization.

Examples of Land Tenure Systems

In The Gambia, each village has an identifiable land area that is administered by the village headman. Any compound can clear unclaimed land outside the village jurisdiction and claim it for the village. Land is passed on through the male lineage. Women obtain land mainly from their husbands, but also receive some from their parents. Men grow groundnut, millet and sorghum, women grow rice and vegetables. Maize is grown by both men and women. Women help with millet and sorghum harvesting and are beginning to grow some groundnut. Seasonal migrants from other parts of the country or Senegal (*strange farmers*) can obtain land for cropping in return for working several days each week on the fields of the compound head; they return to their own villages at the end of the cropping season (Norem *et al.*, 1988, pp. 303-304).

Among the Fula and Mandinga in Guinea-Bissau, land is collectively owned by the resident clans of the village and allocated by the male elders to individual compounds; the male compound head allocates it to the individuals within the compound. Usufruct rights can be granted on a collective or individual basis. Both men and women, married or not, can obtain use rights to individual plots and the right to dispose of the harvest from these. Collective fields remain under the control of the compound head who is responsible for maintaining the collective granary, and work on collective fields has priority over work on individual plots. Grasslands around the settlements are cropped exclusively by men, in a grass-fallow rotation of 4-8 year cycles, with sorghum, millet, fonio, cassava, peanuts and cotton. Male collective fields must be planted with subsistence crops (millet, sorghum) to be consumed, rather than sold. Male cash crops (groundnuts, cotton, cassava) are grown only on males' individual plots. Upland forest areas are used, with men and women working together, in long-cycle slash-and-burn shifting cultivation to grow upland rice, millet, maize and tubers. River valley land with sufficient moisture is utilized and controlled exclusively by women; they make all planting decisions and have the right to distribute and/or sell the product from their individual fields. Female collective and individual fields are always located in the valley bottoms and used for rice cultivation. The clans' senior women allocate this land to the compounds, and the senior woman of each compound is responsible for the compound's collective fields and allocates the individual fields to the compound's women. The senior women also have the rights to the oil palms in the valley bottoms. All women receive from the village elders rights to water and land for their gardens where they grow vegetables; they have the right to dispose of the produce of their garden. Some men produce cassava, cocoyam (taro), maize, sweet potato, and beans in their own gardens (Lifton, 1991, pp. 1-19).

In Tanzania, land was traditionally controlled and allocated by patriarchal clan leaders to heads of households or extended families. Today, all land is owned by the state, and the "Village Act" requires that each member of the village, male or female, be assigned separate plots to cultivate specific crops that are designated in the village by-laws. It is reported to be widespread practice for land to be allocated to male household heads who in turn assign plots to wives, sons and daughters. Often, vestiges of the traditional system remain, and the original users, usually males, retain some right over land even if it is currently lying fallow (Mtoi, 1988, p. 346).

Among the Bemba in Zambia, land holdings are semi-permanent. Local chiefs allocate land according to farmers' ability to cultivate (notably availability of draft power). Tenure is based, thus, on customary rights allocated by local chiefs and secured through clearing and continuous use. Land use rights are passed on through the matrilineal kinship system. Farm sizes are large, averaging close to 100 ha, but only about 5 percent of the farm is actually cultivated at any given time (Hudgens, 1988, pp. 373-387; Sutherland, 1988, pp. 389-406).

4.19 Reality is far more complex. There is a wide diversity of farming systems in Sub-Saharan Africa, determined by differences in population density, agro-ecological conditions, socio-political organization, lineage and descent definitions, inheritance and residence patterns, agricultural technology, and degree of commercialization. The correspondingly wide range of seemingly different land tenure systems is therefore not surprising. There are, however, important similarities among most of them. Most define land rights, particularly ownership rights, for groups. Individual or family use rights rest on customs recognized by the group. The group, not the individual, owns the land -- although there is no formal recording or land titling. An individual's entitlement to the land is transitory, although in most cases lineages enjoy continuous use rights over specific parcels. As fallow periods become shorter and cultivation of plots becomes more continuous, land is increasingly retained by families, households or individuals and transferred or bequeathed under prevailing customary rules (Migot-Adholla *et al.*, 1991). There is, thus, gradual institutional change in response to rising population pressure and this change accompanies and facilitates the evolution and intensification of agricultural production.

4.20 Customary tenure systems involve important intricacies. Ownership, management responsibility and use rights are often not identical. Use rights to different products from the same piece of land may be vested with different individuals or groups. Pastoralists and sedentary farmers may coexist on the same land, with farmers having cultivation rights and pastoralists grazing rights after crops are harvested. On the same plot of land, the right to the products of trees and the right to plant crops may be quite distinct and vested in different individuals or groups (see para. 4.23).

4.21 Where, under traditional tenure systems, usufruct rights are acquired simply by clearing and cultivating land, the incentive has been strong for settlers to move into previously uncultivated forest or savanna areas and to clear the land quickly in order to strengthen their claims and weaken those of other potential (even current) users.⁴ This extends cultivation to marginal lands and imposes costs on the previous users -- often pastoralists or traditional forest dwellers. As fallow periods shorten or valley bottoms are taken under cultivation, land rights of farmers tend to take precedence over those of herders who are then forced to remain on more marginal and more rapidly degrading rangeland. Where sedentary farmers and transhumant herders have coexisted in symbiotic land use systems, the incorporation of livestock activities into settlers' farming systems also tends to cause difficulties for the pastoralists who are then increasingly compelled to keep their herds on pasture land alone. As a result, soil fertility declines more rapidly on such range land (Gorse and Steeds, 1987; Stocking, 1987; Falloux and Mukendi, 1988; Nelson, 1988; Mortimore, 1989a and 1989b).

4.22 In many traditional tenure systems, land for farming is assigned to eligible claimants on the basis of their ability to clear it and to establish field crops. In others, bush or forest fallows tend to revert to communal authority and can be reassigned to another claimant. The shortening of fallows may therefore also be the result of the cultivator's attempt to safeguard his/her rights to the plot. It

⁴ In Mali, farmers plough more land than they actually intend to crop in order to establish and protect their land use rights for the future. Ploughing without establishing crops renders the land even more vulnerable to erosion than if it were actually cropped. In Nigeria, large tracts of land for which members of the political and economic elite have obtained occupancy certificates under the provisions of the 1978 Land Use Act are rapidly cleared of vegetation with motorized equipment so as to preclude any possibility of smallholders remaining or becoming active in this area. This is an effective way of eliminating potential contestants to the land claimed under the provisions of the Act, but it also is extremely abusive of the environment. Even under government-sponsored land development schemes, the ability to clear, rather than to develop, the land is often a key determinant of eligibility. In Sudan, for example, the parastatal Mechanized Farming Corporation has been awarding 15-year leases only to people who clear 85 percent of their assigned holdings in three years (Southgate, 1990).

may also be caused by someone else moving in too soon after the previous cultivator has left the plot to natural regeneration because the land is becoming scarce.

4.23 Understanding the complexities of traditional local tenure systems is especially important for understanding the incentive system that applies to agro-forestry interventions. It also often helps explain deforestation. Tree tenure may be distinctly different from land tenure.⁵ One person or group may have rights to the land, while others have rights to the trees on it, or to certain products from certain trees at certain times. In northern Sudan, for instance, a tree and its fruits may belong in shares to the owner of the land, the person who provided the seedling, and the owner of the waterwheel that irrigates the land (Gregersen *et al.*, 1989, p. 156). In some systems, tree clearing may be the only way to establish uncontested usufruct rights for cultivation. Elsewhere, tree planting may be regarded as laying claim to land. In many areas, diverse arrangements concerning rights in trees are common and of considerable relevance to those deciding whether or not to plant trees – and which trees.⁶ Tree tenure issues are particularly critical where deforestation is severe and the fuelwood crisis pressing, but also where tree crops have potential for environmentally sustainable and at the same time profitable agricultural development. In some countries, because all forest land is owned by the state, people fear that if they plant trees their land will revert to the government. In parts of the Sahel, people have been unwilling to plant certain trees because they are on the forest department's protected list, and to crop or prune them would require going through tedious procedures to prove they own the land and planted the trees and to obtain a cutting permit (Timberlake, 1986).

4.24 A recent World Bank study in Ghana, Kenya and Rwanda found that traditional land tenure systems do not appear to be insecure (Migot-Adholla *et al.*, 1991). Many farmers enjoy transfer rights on their lands – although these rights may be subject to approval by family or lineage members. To the extent that the social system sanctions transactions in land, such transactions are sufficiently recognized. Traditional tenure systems continue to evolve, and many have over time accommodated increasing degrees of individual ownership and management control. Rapid population growth and growing commercialization of agriculture increasingly necessitate investing in land management and improvement, hastening the individualization of land rights (Migot-Adholla *et al.*, 1989).⁷ In many cases, private rights to land have become virtually exclusive, although they fall short of outright ownership.⁸ Other members of the community may have secondary concurrent or sequential rights that permit, for instance, fuelwood collection or livestock grazing. Inheritance has

⁵ See Raintree, 1987, for a number of detailed tree tenure studies in Sub-Saharan Africa.

⁶ Tenure rights in trees comprise a variety of specific rights, primarily those of creation (i.e., planting), use and disposal. Use rights include: (a) gathering rights -- e.g., the right to gather or lop dead branches for fuelwood, to gather things growing on a tree (such as fungus or insects), or to gather tree products from under the tree, such as fallen leaves or fruit; (b) use of the standing tree -- such as hanging honey barrels in it; (c) cutting parts or all of a living tree -- e.g., for livestock fodder or building material; (d) harvesting produce. The disposal right comprises: (a) the right to destroy (by uprooting or felling individual trees) or the right to clear a section of forest; (b) the right to lend; (c) the right to lease, mortgage, or pledge; (d) the right to bequeath; (e) the right to sell (Gregersen *et al.*, 1989, pp. 155-157).

⁷ There are exceptions -- still found, for example, in south-eastern Nigeria or western Sudan -- where individuals and families may be given access to an amount of land but not a specific plot. In such systems, where use rights for cultivation of seasonal crops rotate each year or after several years, individuals may not be keen on making long-term investments in land improvement (Migot-Adholla *et al.*, 1989).

⁸ Women's tenurial security is generally far less certain than that of men -- although the opposite may be the case in some matrilineal-matrilocal societies.

emerged as the most significant form of acquisition of agricultural land in traditional rural society, and rights to such land are very secure; nevertheless, security of tenure is strengthened by continuous occupation and cultivation. Restrictions on the sale of inheritable land may still apply in some systems (as in the northern Mossi Plateau in Burkina Faso), but in others land has been sold for half a century or more and can be mortgaged and leased (as in the Hausa areas of southern Niger). Purchases are becoming an increasingly important means of acquiring land. This is occurring in Kenya, with its history of land registration and government intervention in land matters, but also in Ghana and Rwanda, where governments have been less active in providing and enforcing a well defined legal framework for land transactions (Migot-Adholla *et al.*, 1989).

4.25 Problems arise as traditional tenure systems begin to impose constraints on evolving agricultural production systems and the adoption of technological change. Unfortunately, most African governments and most donors have mistakenly believed that traditional community ownership of land did not provide adequate tenurial security, and that it discouraged investment in the land. This perception arose largely from the failure to understand fully the intricacies of traditional tenure systems and the often subtle, but important differences among different communities' arrangements. A particularly important aspect of most, if not all, traditional African land tenure systems – the concept of the inalienability of land – has been widely regarded as an obstacle to agricultural development. Land markets did not readily develop, therefore, and land ownership was difficult to establish as collateral for institutional credit.

4.26 There has also been an erosion and breakdown in customary laws and rules governing sustainable use and management of land and other common property resources. This has occurred under the pressure of rapid population growth and has been exacerbated by large-scale migration in many countries as well as by changes in social values and customs. Increasing commercialization of agriculture has induced changes in land use, farming systems and cropping patterns. Inappropriate pricing signals arising from government interference in input and output markets have often hastened such changes into unsustainable directions. And central political authorities have frequently undermined the capability of local decision-making bodies to manage their natural resource environment by imposing tight controls over local organizations, removing authority to central agencies, and creating new organizations that compete or conflict with traditional ones (Blaikie and Brookfield, 1987; Gorse and Steeds, 1987). In many areas, resources that were under effective communal management have, as a result, been converted into *de facto* open-access resources.⁹

There is much misunderstanding of the difference between common property and open access regimes. Open access resources are at great risk of over-exploitation, since they lack clearly defined ownership and use rights assignments as well as effective management. Common property systems, by contrast, are well-structured arrangements in which group size is known and enforced, management rules are developed, incentives exist for co-owners to adhere to the accepted arrangements, and sanctions work to ensure compliance. There is a set of agreements within the community over the rights to use of communal land resources by various members and/or sub-groups of the community and by *strangers*, even in sparsely settled areas. Communal land really means not so much communally managed land, but land to which members of the community have rights, while outsiders do not or only under specific and tightly prescribed conditions (Repetto and Holmes, 1983; Blaikie and Brookfield, 1987; Bromley and Cernea, 1989; Barnes, 1990a).

9

4.27 The response of many governments has been to nationalize land ownership, but then to allow customary law to guide the use of some land, while allocating other land to private investors, political elites and public projects. This has reduced, not increased, tenurial security. Investing in the land becomes risky for farmers, since governments can and do reallocate land to serve "national

⁹ Nekby (1990) describes this situation in dryland areas.

purposes". In many cases this accelerates the breakdown of customary land management systems and emergence of open-access situations in which exploitation by anyone is permitted. Open-access systems, found especially in forest and range areas,¹⁰ result in rapid environmental destruction — a repetition of the process widely observed before the agricultural transformation in Europe and usually (albeit mistakenly) labeled "the tragedy of the commons." Users of such resources have no incentive to limit their exploitation because they cannot be certain that others will similarly curtail theirs. Open-access systems are not conducive to resource conservation or investment in land. This problem was resolved in Europe largely by the allocation of land to individual owners who then had an incentive to invest in it, develop it and conserve it.

4.28 As noted earlier, there may be a further problem in open access systems, which may also be a problem of traditional tenure systems. Granting access to land for cultivation to members of a community on the basis of ability to cultivate it may be a disincentive to control human fertility, because the ability to cultivate is generally determined by the ability to mobilize family labor (e.g., Amankwah, 1989, p. 21).¹¹ Field studies report this to be an important incentive to increase family size through polygamy and/or pressure on women to bear many children.

4.29 The "solution" often proposed to solve these problems is the allocation of individual land titles, through large-scale titling programs. But the experience with such programs has been poor. Individualized land titling in Kenya and Botswana has facilitated land grabbing, concentration of ownership and concomitant landlessness. Such land grabbing had been practiced by European colonists, and some of the new elites often used the same methods. However, the problems in Kenya and Botswana may be associated more with the problem of transition from traditional to modern tenure systems. The rights of traditional land and tree owners were largely not respected in Kenya and Botswana, and members of the political and economic elite too easily manipulated the legal and administrative systems to wrest land from its traditional owners. However, once obtained, individual land ownership does provide an incentive to develop and maintain the land. This can be witnessed, for instance, in the intensive sustainable farming practiced by smallholders in the Kenya highlands, by private landowners in Zimbabwe and Botswana, and on tree crop plantations in Côte d'Ivoire.

4.30 To avoid the problems associated with an excessively rapid move to private individual land titles, or the even greater problems of nationalization of land ownership, it will be prudent to establish legal protection of traditional tenure systems, combined with a mechanism to provide individual or group titles on demand and only with the agreement of the traditional land owners and users (such as pastoralists). Only a demand-driven process of individual land titling will be possible and advisable in Sub-Saharan Africa. However, as traditional land tenure systems break down, and to resolve existing problems in open access systems, land titling will be necessary for agricultural growth, soil conservation and forest protection.

¹⁰ In much of the West African Sahelo-Sudanian Zone, pasture and even crop land are often treated as a free good under current policies. Wells have been sunk to permit access to ostensibly un- or under-exploited rangeland, and settlers in less densely populated areas are not subject to any land-use guidelines. In both cases, legal incentives would help by offering land rights in exchange for management responsibilities (Gorse and Steeds, 1987). In most countries, forest land has been taken over by governments, overriding the rights of indigenous populations. Though nominally controlled, these "protected" or "reserved" forests have become virtually open-access resources for large- and small-scale exploitation, because the responsible agencies have not been able to provide effective management (Repetto and Holmes, 1983).

¹¹ Access to non-family labor is limited in most of rural SSA. Hiring wage labor is rarely an option, simply because there is, as yet, no "class" of landless laborers, although population pressure is leading to the emergence of seasonal and migrant wage labor in many countries. More common in many communities is the traditional practice of pooling labor for certain tasks, sometimes among gender and age mates within a village, more often among members of a larger kinship group.

E. Deforestation, Fuelwood, and the Nexus

4.31 In arid and semi-arid areas, the need for woodfuel is a major cause of the reduction in tree cover. Excessive lopping and felling, combined with poor regeneration capability, have set in motion a downward trend that has been sharply accelerated by prolonged periods of drought and increasing livestock pressure on young regrowth. Woodfuel extraction considerably exceeds natural regrowth in many areas. Fuelwood shortages in fact limit the "carrying capacity" of arid and semi-arid West Africa more than do low crop and livestock yields (Gorse and Steeds, 1987, pp. 13 & 28).

4.32 Woodfuels are the staple source of household energy, with 90 percent of all households using them for cooking, the main end-use of energy in Sub-Saharan Africa (Barnes, 1990a). Some agro-processing and rural artisanal and semi-industrial activities (e.g., fish smoking, shea nut processing, pottery, brick making, smithies, beer brewing, etc.) also use considerable quantities of woodfuels.¹² In many countries, woodfuels are used in industrial production as well (tanneries, cigarette and match production, breweries, tea factories). In the early 1980s, wood accounted for over three fourths of total energy supply in 13 of Sub-Saharan Africa's 16 least developed countries (de Montalembert and Clement, 1983). In urban areas, charcoal is partly replacing wood.

4.33 The fuelwood problem is a function primarily of population density and of agro-climatic and vegetation zone and is, therefore, very region- and location-specific. A 1983 FAO study (de Montalembert and Clement, 1983) identified the regions where people faced acute fuelwood scarcity or deficits.¹³ The most vulnerable areas include the arid and semi-arid zones south of the Sahara as well as eastern and southeastern Africa and the islands and mountainous regions. Fuelwood deficits were identified in the savanna regions of West, Central and East Africa. The number of people affected by fuelwood shortages, already large, is expected to increase steadily:

- The arid regions face the most severe problem – where the woodfuel scarcity is a more severe limit on the land's carrying capacity than food production capability.
- In the more densely populated savanna zone, only 25 to 50 percent of total fuelwood needs can be met from annual regrowth; conditions for tree regrowth are generally favorable, but rapid population growth is causing problems.
- In the less densely populated savanna, supply is still adequate for the resident population, but needs could rapidly outstrip supply in the absence of appropriate interventions.
- In Central Africa, with tropical forests and low population densities, woodfuel supplies are likely to be adequate well into the next century. However, increasing rates of cutting are contributing to deforestation and the resulting environmental problems.
- The coastal strip along the Gulf of Guinea has excellent conditions for tree growth, and tree plantations are widespread. Fuelwood supply is adequate, but this will change in the near future, especially around the large and rapidly growing urban concentrations.

¹² In Malawi, 100 kg of firewood are used to cure 3-12 kg of tobacco; in Côte d'Ivoire, 100 kg of wood are used to smoke 66 kg of fish (Dankelman and Davidson, 1988).

¹³ Populations facing "acute scarcity" were defined as those in areas where energy requirements could not be met even by taking wood on a non-sustainable basis or by making use of animal waste. Populations facing a fuelwood "deficit" are those in areas where fuel needs were met by taking wood on a non-sustainable basis.

- The densely populated highlands of Eastern Africa already face woodfuel deficits. Reforestation efforts in Burundi and Rwanda have been rather successful, but unable to keep pace with demand growth.

4.34 In 1980, eleven countries faced negative fuelwood supply-demand balances: Burkina Faso, Burundi, Chad, The Gambia, Kenya, Malawi, Niger, Rwanda, Swaziland, Tanzania and Uganda (Table 19). By the end of the century Ethiopia, Madagascar, Mali, Nigeria, Senegal, Sierra Leone, Sudan and Zimbabwe are expected to join this list. Since a significant switch to other fuels is not likely or possible in the short to medium term, population growth translates almost directly into a growth in demand for woodfuels (except to the extent that fuel use efficiency is improved). Yet continued reliance on woodfuels is clearly threatened in many regions by unsustainable exploitation.

4.35 Over time, urbanization will facilitate a switch to non-wood fuels, but urban Africa still depends very heavily on wood. Woodfuels are the fuel of the poor, including the urban poor. In many cities, as much as 90 percent of all households use woodfuels for cooking. Fuelwood prices in urban areas are high and rising. In some cities spending on fuelwood now claims up to 20 percent of the income of poor households. Urban demand for woodfuels has been far more destructive of forest resources than rural fuelwood gathering, mainly because of inappropriate policies. Rapid urban growth has led to intense cutting of wood on a large scale around cities and along the major roads. Wood is brought from considerable distances, charcoal from even farther, and there are increasingly wider rings of deforestation around cities such as Ouagadougou, Dakar and Niamey. Woodfuels are supplied to major cities in eastern Africa such as Mogadishu from as far as 500 km away. Since the wood itself is virtually cost-free to commercial suppliers, the cost of trucking woodfuels to urban markets is the main determinant of the distance from which woodfuels are brought. The commercialization of the urban fuelwood and charcoal economy has increased the utility of rural fuelwood sources: under subsistence conditions, local fuelwood resources were used only to meet local demand, but these resources can now also be exploited for sale outside.¹⁴

Woodfuel prices to "producers" (usually collectors or exploiters of forest resources, rather than actual producers) tend to be extremely low (often as low as 5-6 percent of the urban consumer price) -- providing no incentive to produce fuelwood on a commercial basis. Transport costs and profit margins account for most of the cost to urban consumers. Given the wide spread between the stumpage price and the consumer price, higher stumpage fees, providing incentives for more efficient harvesting and for fuelwood production, would have little impact on urban consumer prices (Barnes, 1990a).

4.36 As studies in Botswana, Malawi, Nigeria and Tanzania have confirmed, woodfuel demand first increases with rising income and later declines with increasing substitution of kerosene, liquefied petroleum gas (LPG) and electricity. The potential for such interfuel substitution depends heavily on economic growth and on income distribution in cities where economies of scale can be realized in meeting demand for fuel from such alternative sources. It also depends on pricing policies and supply security at the consumer level (Barnes, 1990a). To the extent that slow economic growth and rapid population growth prevent significant increases in average per capita incomes, demand for woodfuels will continue to increase about as rapidly as population growth. Moreover, even if aggregate economic growth can be accelerated, but is inequitable and leads to widening disparities in income distribution, this will impede the switch to non-wood fuels.

¹⁴ Limited and inelastic subsistence demand is replaced by limitless and elastic export demand (from the standpoint of the local economy), leading to much more rapid rates of exploitation than would be implied by local population growth alone (Repetto and Holmes, 1983). The collection of fuelwood and its sale in urban/peri-urban areas by poor rural women, on their own account or under wage contract to commercial traders, is an obvious example.

4.37 The brunt of the fuelwood crisis falls on women: they must manage household energy needs through fuel collection, preparation and use.¹⁵ Children increasingly have to help with this task. Girls in particular have to help in fuelwood fetching, fuel preparation, cooking and tending the fire. In Tanzania, girls help their mothers as soon as they can walk. In many parts of Africa it is not uncommon for mothers to take their daughters from school to help them gather fuel. Women (and children) have to walk increasingly further and take more time to collect fuelwood.¹⁶ This time is diverted from other pressing tasks -- including timely crop planting and weeding (thus depressing crop yields) and child care (which is increasingly entrusted to school-age girls kept at home). When fuelwood sources were more abundant, fuel gathering could often be combined with other activities, such as walking home from school or from the market or field. With increasing scarcity, fewer sources and longer distances, the loads carried become larger and heavier,¹⁷ more time is required, and the opportunity to combine wood fetching with other tasks is reduced.

4.38 Fuel scarcity leads to changes in nutritional patterns, especially to fewer meals being cooked and/or meals being cooked less well (Timberlake, 1986, p. 34). This has nutritional and health implications. In the Sahel, many families have gone from two to only one cooked meal per day (Agarwal, 1986); others mix uncooked millet with water for a midday meal (Tinker, 1987). A study in Rwanda found that 62 percent of families cook only once a day and 33 percent cook even less frequently (Dankelman and Davidson, 1988, p. 71). Fuel shortages also induce shifts to foods which require less energy to cook, but may be less nutritious. Women in Burkina Faso refused to use soybeans for food because of the long cooking time and greater fuel requirement compared with the traditional cowpeas (Hoskins, 1979) -- until someone taught them how to ferment the beans into soybean cake which reduced the heating time from as much as 12 hours to only one hour (Tinker, 1987). Switching to raw or partially cooked food or to cold leftovers is becoming more common (Dankelman and Davidson, 1988, p. 71). The shortages of fuelwood, of food and of women's time combine into a serious nutritional and health problem. Partial cooking can cause significant health problems. Water purification also requires boiling -- not possible without fuel and time. Hot water to wash dishes, utensils, laundry and children may be out of the question (Dankelman and Davidson, 1988, pp. 71-72). The impact of nutritional and health problems on labor availability and productivity for agriculture and other income-generating activities is, of course, negative.

4.39 The intensifying fuelwood shortage has another important negative effect on rural women. Many of their non-farm income-earning activities require fuelwood: food processing, beer brewing, fish smoking, pottery, etc. Fuelwood scarcity therefore severely constrains their opportunities to supplement their income through such activities. This is an increasingly critical issue in view of the widespread gender-separation of budgets and women's almost exclusive responsibility for child rearing (see Chapter V).

¹⁵ Men do not usually involve themselves in fuel provision for the household under subsistence conditions, but there are exceptions. They usually take over only when the fuel economy becomes commercialized.

¹⁶ In parts of Sudan, the time needed to fetch fuelwood increased more than fourfold between the mid-1970s and the mid-1980s (Agarwal, 1986).

¹⁷ Women very rarely have access to any labor-saving technology for their task -- transport aids or efficient cutting tools for cutting or felling. They carry heavy loads to reduce the number of trips required to provide fuel for their household (and often their non-farm income-earning activity as well). They may headload as much as 35 kg (even though in many countries 20 kg is the maximum legally permissible headload for women) over distances of up to 10 km, often over difficult terrain. Carrying such heavy loads damages the spine, causing difficulties during pregnancy and childbirth, uses up substantial energy, and is a cause of frequent accidents.

4.40 Eventually, women have little choice but to switch to other fuels. Interfuel substitution in rural Sub-Saharan Africa usually means a switch to less efficient fuels — most commonly to crop byproducts and residues and dung which are far more valuable if recycled as inputs into the farming system to help maintain soil fertility. Many such fuels are less convenient than firewood or charcoal, requiring more tending and fire-feeding, generating more smoke and less heat, etc. Cooking may take longer and require even more fuel than before. Diverting them to use as fuel has significant negative effects on soil fertility, water retention, crop yields, and soil degradation and erosion. This is increasingly happening, for example, in areas such as the Ethiopian highlands and the northern part of the Sahelo-Sudanian Zone.¹⁸ The importance of agricultural wastes and dung for fertility management in farming systems is particularly critical as fallows are shortened and recycling of crop waste and dung becomes essential in the move towards agricultural intensification. Under the agro-ecological conditions of much of Sub-Saharan Africa, this is extremely important: organic matter is quickly mineralized in the absence of shading tree canopies, and nutrients are leached rapidly from most soils.

4.41 There are many causes for the fuelwood problem, including the traditions of its use and the absence of alternative fuels. The major reason for the lack of success in introducing alternative fuels is that wood has been regarded in most of Sub-Saharan Africa as a free good, taken largely from land to which everyone has the right of access ("open access" land). As a result, a market for fuelwood has not developed in many countries despite its increasing scarcity. Even where fuelwood scarcity and high transport costs have created a market, the "producer price" of wood has remained below its replacement value because most supplies come from open-access forests. Market prices do not include the environmental costs of heavy fuelwood extraction. Alternative energy sources, such as kerosene, liquefied petroleum gas (LPG) and electricity are costly; their cost more closely reflects their scarcity value since they are not obtainable in "open-access" form. Despite dwindling forests and wood supplies, other fuels are not substituted in significant quantities, because the price of fuelwood is lower than that of alternative fuels. Investments in kerosene, LPG and electricity supply systems must be made more efficient to make them more price competitive with fuelwood. Fuelwood prices, conversely, need to be increased. Chapter VIII suggests ways how this can be done.

F. Logging

4.42 Commercial logging also takes a heavy toll — in large part because of inappropriate logging policies and practices. It is, in fact, probably not so much the quantity logged but rather the procedures used that are the chief cause of forest destruction.¹⁹ Logging concessions are often awarded as a form of political patronage. Logging practices are rarely monitored or controlled, and abusive logging practices are so common as to have become the norm (Repetto, 1988a; Spears, 1988). Stumpage fees tend to be very low, further encouraging extensive and destructive logging (Grut, Gray and Egli, 1991). Replanting is rare, because there is neither an incentive nor a requirement to do it. Concession agreements usually require neither replanting nor maintenance of concession areas as a forest. Most are also too short in duration to provide any inducement to the concessionaires to manage the concession areas for sustainable long-term multi-cycle production. Concessions are often abandoned once mined. In some cases, governments subsidize logging through

¹⁸ In Ethiopia, an active urban market for animal dung has developed where fuelwood resources have become depleted (Anderson and Fishwick, 1984). One study estimated that dung used as fuel in Ethiopia in 1983 would have increased the country's cereal output by 1-1.5 million tons if it had been used as fertilizer instead (Newwombe, 1989, p. 132).

¹⁹ Commercial logging by itself is responsible for only about 10 to 20 percent of forest destruction in Sub-Saharan Africa, but it has been considerably more destructive in some countries, such as Côte d'Ivoire.

tax and duty exemptions and through governmental financing of roads and infrastructure in forests. Subsidies provided to wood processing industries have the same effect. Areas closer to ports appear to be most abused, with high transport costs probably the most important factor protecting inland forests against logging in parts of Central Africa.

4.43 There is widespread agreement among students of the situation that logging in tropical forests, as presently practiced, is not consistent with the sustainability of rainforest ecosystems. It has been argued that logging itself, if properly undertaken, need not necessarily destroy the forests. However, recent surveys suggest that there are no sustained-yield forest management systems practiced on any sizeable scale in Western and Central Africa (Goodland, 1991, p. 14; Besong and Wencélius, 1992). Even selective logging for certain species and/or trees of certain size is prone to disrupt these fragile ecosystems with their multitude of highly specialized life-forms and of intricate multiple symbiotic relationships so severely that they will not survive intact. Although less directly linked to the Nexus, population growth will stimulate more logging, with its significantly negative impact on the environment. Through the environmental impact may come declines in rainfall, increases in water run-off and, hence, declines in agricultural yields (see Chapter II).

4.44 Logging almost invariably leads to a second -- and usually even more damaging -- phase of forest destruction. Logging roads provide access for land-hungry settlers into areas previously difficult to enter. Moving along and spreading out from the logging roads, landless or shifting cultivators rapidly take over logged-over forest areas, clear the remaining vegetation and convert the land to agricultural uses -- usually at very low levels of productivity. This accelerates and expands the process of deforestation begun by the logging companies. Logging concessionaires ordinarily acquire rights to log from governments, ignoring the traditional land and forest rights of forest dwellers. These rights, once eroded, are not respected by new settlers penetrating along the logging roads.

4.45 In virtually all countries of Sub-Saharan Africa, the institutions charged with managing and protecting national forest resources tend to be very weak. Forest guards and rangers often have neither the operating resources nor the training even to monitor adequately what is happening in the forest. They are even less well equipped and prepared to regulate logging companies, deal with poachers, assist forest dwellers, and prevent encroachment of land-hungry settlers. These institutional weaknesses are so grave that even in many parks farmer encroachment and logging occur on a significant scale. Forest services have little capacity to plan, to levy taxes, to undertake land use surveys, to deal with land disputes in forests (Besong and Wencélius, 1992).

4.46 The causes of the logging problem are related to those of the fuelwood problem. Forests have been widely regarded as reservoirs of free goods to be mined. Governments share in the bounty with private loggers through stumpage fees and taxes. However, once the forest disappears, the environmental services it provides disappear with it. It is disappearing fast.

Statistical Analysis to Explain Inter-Country Variations in Crop Yields

1. Many of the relationships described in this chapter cannot be investigated statistically using aggregated data. However, limited testing may establish the plausibility of the hypotheses:

- Crop yields should be higher where population is growing most rapidly relative to cultivated land. People begin to intensify agriculture as cultivable area per person declines. Hence, statistical analysis should show an inverse relationship between area cultivated per person and crop yields (all other things equal). However, the rate of growth in yields stimulated by declining availability of cultivable land per person will be significantly lower than the rate of population growth.
- Efforts to stimulate intensification, through the use of fertilizer, for example, will significantly accelerate the increase in crop yields beyond the growth rate stimulated by rising population density alone. This should be observed as higher yields in countries using more fertilizer (all other things equal).
- Primary school education, of men and women, should facilitate farmer adoption of intensive farming techniques and therefore be associated with higher crop yields.
- *Ceteris paribus*, countries with more rapid degradation of their natural resource endowment, as reflected in higher rates of deforestation, should have lower crop yields.
- Finally, countries with a policy environment more accommodating for profitable market-oriented farming should have higher crop yields than countries with less conducive policies.

2. These hypotheses were tested by determining the statistical relationship between cereal yields (averages for 1984-1986) as the dependent variable, using as independent variables: cultivated area per person (average 1965-1987), fertilizer use per ha in 1987/88 (fertilizer use remained fairly stable in the 1980s), percentage of the school-age population in primary school (average 1965-1987), the rate of deforestation in the 1980s, and the general "appropriateness" of agricultural policy during the period 1980 to 1987. (The methodology applied is described in more detail in the Annex, which also presents the data used for this analysis.) Except for the rate of deforestation, the values for each variable were converted to their natural logarithm and a regression equation was fit to these data; the coefficients reported below therefore represent elasticities. Policy appropriateness is represented by a dummy variable having the value 1 for countries where policy is judged to have been conducive to profitable agriculture, and 0 where it is judged to have been inappropriate. Of the 38 countries considered, 24 were judged to have pursued inappropriate policies, 14 appropriate. This rating of countries is consistent with the categorization by the World Bank; it is, however, highly subjective. The role of women in agriculture and the effect of the land tenure situation could not be quantified and therefore were not tested in their impact on yields.

3. The equation is as follows, where the dependent variable is average cereal yields in 1984/86 (natural logarithm):

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	5.45	10.1	1%
Cultivated ha per person (a)	-0.33 (b)	2.5	2%
Fertilizer use per ha (a)	0.10 (b)	1.7	10%
Primary school enrollment rate (a)	0.17 (b)	1.2	24%
Deforestation rate	-0.05	0.9	39%
Agricultural policy dummy	0.30	1.9	7%

Adjusted R squared = 0.45

F Statistic = 7.0

(a) Converted to natural logarithm.

(b) Represents elasticity.

4. The equation explains about 45% of the differences in cereal yields among the 38 countries. The unexplained portion will be due to rainfall differences between countries, to differences in the role of women in agricultural production systems, to differences in land tenure problems, to differences in soil degradation and soil fertility, and to data problems.

5. Consistent with the hypotheses, the lower the cultivated area per person, the higher are cereal yields, all other things being equal. The statistical relationship is highly significant, with a T-statistic of 2.5 and with a 2-tail significance test of 2% (indicating only a 2% probability that the coefficient is actually zero and a 98% probability that it is not zero). It suggests that the pressure to intensify production mounts with increasing population density on cultivated land; it is true even when the use of fertilizer and other modern inputs, the policy environment and primary school enrollment rates are held constant. This reflects farmers' ability to respond to rising population density with simple innovations. But, also consistent with the hypotheses, the coefficient is less than 1, suggesting that a 3.1% annual decline in cultivated area per person (due to population growth at this rate) will only stimulate people to intensify farming at a rate of about 1% per year -- i.e., much slower than the rate of population growth itself. Historically, this is what happened. Crop land expanded at less than 1% p.a., and yields increased on average by slightly more than 1% p.a., giving an agricultural output growth of only about 2% per year for SSA as a whole for the 1965-1990 period.

6. A 1% increase in fertilizer intensity is associated with a 0.1% increase in cereal yields. The coefficient is significant statistically (2-tail test of 10%, indicating a 90% probability that the coefficient is not zero). Since fertilizer use is extremely low in SSA (averaging 85 grams per ha in 1987/88, compared to China, for example, where it is 2,360 g/ha), there is vast scope for increasing its use. This is also true for other modern tools and inputs, with which fertilizer use is highly correlated; given this correlation, the fertilizer variable also picks up the effect of the use of other modern inputs. Growth rates of fertilizer use (and other modern inputs) of 10-15 percent per year during the next decade are feasible. This would stimulate growth of cereal yields, according to this equation, by between 1.0% and 1.5% per year.

7. A 1% increase in the proportion of primary school-age children enrolled in school is associated with an 0.17% increase in cereal yields. The statistical relationship is weak, but when added to the evidence cited in the text, it suggests the plausibility of better overall educational attainment having a positive impact on farm productivity. This makes sense, since in most SSA countries the majority of the adult population is working in agriculture and associated activities. Further statistical testing will be undertaken with additional data now being compiled.

8. The dummy variable representing agricultural policy adequacy is statistically significant in explaining cereal yield variation between countries. A better policy environment is associated with higher yields, all other things equal.

9. Consistent with the hypothesis, countries experiencing the most rapid deforestation have lower cereal yields, all other things equal. But the statistical relationship shows no significance. Further testing with better data will be undertaken, since the site-specific evidence referenced in the text is strong. The problem may be that deforestation is endogenous. The statistical tests summarized in the following box suggest that deforestation itself is related to population density on cultivated land, intensity of fertilizer use, and agricultural policy. Therefore, when assessing the determinants of crop yields across countries, these other factors are already picking up the impact of deforestation, thus leaving deforestation as such with a coefficient not significantly different from zero.

10. The same equation was tested substituting as a dependent variables the yields of maize, sorghum, rice and cassava, respectively. The results are reported in the Annex. In general, the strength of the correlation between area cultivated per person and yields is confirmed (the larger the area, the lower the yield -- except in the case of irrigated rice where no statistical relationship is evident). Fertilizer use is most effective on maize, but shows no statistical relationship with yields of the subsistence crops sorghum and cassava. A good policy environment is most important for cereals, especially rice and sorghum, but seems to have had little importance as regards cassava. Deforestation has a negative impact on sorghum yields, which are sensitive to environmental problems, but not on rice (grown with irrigation) or cassava (a hardy crop). Primary school enrollment appears to have had no statistical association with the yields of any of the four crops individually tested.

11. The above analysis also suggests the plausibility (though not the likelihood) of achieving 4% p.a. average growth of agriculture in SSA. This could occur from: more labor use per ha facilitated by continued population growth (causing a 1% increase in annual output growth); 1.5% annual yield growth attributable to a 15% annual increase in the use of fertilizer (and of other modern inputs); and a rate of expansion in cropped area of 0.5% p.a. This gives a total output growth rate of 3.5% p.a. An increase in the number of countries with appropriate agricultural policy, and primary school enrollment increasing at 2% per year, should suffice to provide the additional 0.5% annual growth rate required to reach the postulated aggregate target. However, in the long run, as population growth slows, the scope for policy improvement narrows, and further expansion of cropped area becomes less feasible, sustaining 4% annual growth will become more difficult. It will depend increasingly on greater use of modern inputs and equipment, genetic improvements in crops and livestock, and improvements in people's educational attainment. Hence the importance of improved agricultural research and extension and of general education.

Statistical Analysis to Explain Inter-Country Variations in the Rate of Deforestation

1. The analysis in Chapter IV suggests that deforestation is related positively to population pressure on cultivated area (the lower the cultivated area per person, the higher the rate of deforestation), to the rate of population growth (the higher the rate of population growth, the higher the rate of deforestation due to land clearing and fuelwood gathering), and with policies favorable to agriculture (the more profitable agriculture and logging, the more rapid the clearing of forests). It is negatively related with the use of modern farm inputs such as fertilizer (the greater the use of modern farm inputs, the lower the need to clear more forest land for farming). Open access land tenure situations were also hypothesized to stimulate deforestation, but this cannot be measured.

2. To test the above hypothesis, regression analysis was undertaken with the rate of deforestation 1980-1988 as the dependent variable. Independent variables include the number of hectares cultivated per person (average 1965-1987), fertilizer use per hectare (1987/88), the population growth rate (1965-1990), and the agricultural policy dummy variable. The resulting equation is as follows:

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	-0.54	0.41	69%
Cultivated ha per person (a)	-0.60 (b)	1.50	15%
Fertilizer use per ha (a)	-0.19 (b)	1.17	25%
Population growth rate	0.56	1.40	17%
Agricultural policy dummy	0.76	1.65	11%

Adjusted R squared = 0.09

F-statistic = 1.92

(a) Converted to natural logarithm.

(b) Represents elasticity.

3. None of the variables is statistically significant at the 90% level or above (having a 2-tail significance test of 10% or less) in its association with deforestation. But agricultural policy, cultivated land per person and population growth are close enough to the 90% significance level to suggest, when combined with the site-specific evidence noted in the text, the plausibility of the hypothesis. The coefficients are consistent with the hypothesis. However, the overall equation is not good at explaining variation among countries in the rate of deforestation. Numerous other unquantifiable factors are at play, such as the land tenure situation, rainfall, and logging policies. The poverty of the data also reduces the tightness of the fit. Additional data are being compiled to permit further testing.

4. Despite the poor overall fit of the equation, it suggests the possibility that countries with more cultivated area per person have lower rates of deforestation, all other things being equal. Countries with higher intensity of fertilizer use have lower rates of deforestation. Countries with more rapid population growth have higher rates of deforestation. Countries with better agricultural policy have higher rates of deforestation -- implying a trade-off between agricultural growth and deforestation.

5. If further testing with better data confirms the statistical validity of these relationships, it will suggest that slowing population growth and intensifying agriculture would slow the rate of deforestation. Although poor agricultural policy (which usually also entails poor policy for the timber industry) would reduce deforestation, this is not a useful instrument, because the objective of accelerating agricultural growth will override that of reducing deforestation in every country. Hence the importance of environmental action plans and land use planning, which develop mitigating actions to reduce the negative environmental impact of improved agricultural policy, and which should serve to focus agricultural growth into environmentally less destructive channels (Chapters IX and X).

Statistical Analysis to Explain Inter-Country Variations in the Loss of Wilderness Area

1. Table 20 shows the percentage of wilderness area lost since about 1900 in each African country. As in the case of deforestation, it is hypothesized that the degree of wilderness loss is associated with declining levels of cultivable land per person, but is reduced by intensification of agriculture. An improved agricultural policy environment is likely to stimulate the destruction of wilderness area by farmers. In addition, it is hypothesized that better educated people will show more concern about the environment and, hence, that countries with higher rates of primary school enrollment will have lower rates of wilderness loss.

2. Statistical regression analysis was used to explore the above hypothesis, with the percentage of wilderness loss the dependent variable. The result is as follows:

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	76.9	8.8	1%
Cultivated ha per person (a)	-7.2 (b)	1.4	17%
Fertilizer use per ha (a)	-2.6 (b)	1.1	28%
Primary school enrollment rate	-0.2	1.9	7%
Agricultural policy dummy	11.0	1.8	8%

Adjusted R squared = 0.15
F-statistic = 2.5

- (a) Converted to natural logarithm.
- (b) Represents elasticity.

3. The signs of the coefficients are consistent with the hypothesis. But cultivated area per person and intensity of fertilizer use are not statistically significant at the 90% level (i.e., showing a 2-tail significance test of 10% or less). The results are interesting enough, however, to suggest the plausibility of the hypothesis, particularly in combination with the location-specific evidence reviewed in the study. Further testing with additional data has been initiated.

4. The coefficients suggest the possibility that the greater the available area under cultivation per person, the lower the rate of wilderness loss. The higher the intensity of fertilizer use, the lower the wilderness loss. The greater the percentage of school-age children in primary school, the less the wilderness loss. The better the agricultural policy, the more the wilderness loss. However, the overall equation explains only a small part of the variation among countries in wilderness loss. Factors such as land tenure, expanse of parks and reserves, Government efficiency in managing parks and reserves, and development of infrastructure in wilderness areas are likely to affect the maintenance of wilderness area. Data problems also explain some of the lack of fit.

5. If further testing establishes the statistical validity of these findings, the operational conclusion will be that a reduction in the rate of growth of population, intensification of agriculture, and expanded primary school education would reduce the speed of wilderness loss. Since it would not be legitimate to distort agricultural policy in order to conserve the remaining wilderness areas, the negative impact on the wilderness of favorable agricultural policy will have to be offset. This again underscores the importance of environmental action plans and land use planning. Unfortunately, the statistical analysis tells nothing of the need for land tenure reform, the desirability of expanding protected areas, and other actions to conserve the wilderness.

V. THE ROLE OF WOMEN IN RURAL PRODUCTION SYSTEMS

A. Introduction

5.1 A central aspect of the population-agriculture-environment Nexus is the role of women:

- in their traditional child bearing and rearing role, women directly influence both the size and the quality of the future stock of human resources;
- in their household management role, women are the primary managers and users of a variety of natural resources (most notably fuelwood and water);
- in their farming role, women are responsible for a very substantial share of foodcrop production and a variety of other agricultural activities, and their decisions and activities have a direct bearing on soil fertility and erosion, water infiltration and retention, and waste and by-product recycling.

5.2 Women's triple role – child bearing and rearing, household management, production activities – and the increasing pressures on their time and energy have important consequences for human resource development, agricultural productivity and environmental sustainability. As their agricultural work load grows, women face rising pressures in their role as household managers, and their childbearing and child caring burden remains as heavy as ever. Technical, legal and institutional developments have added further constraints on women (e.g., land titling, access to credit and extension, research orientation, etc.). The promotion of cash crops, mechanization, extension and formal credit systems have mainly been directed at men. As men turn to non-farm work, women increasingly become *de facto* managers of the family farm. In many areas, 50 percent and more of all farms are managed by women – yet traditional and legal constraints remain severe. Fuelwood and water supplies are becoming increasingly scarce, and more time is required to obtain them.¹ The intensifying time constraint means that women either reduce the time spent on certain tasks or depend increasingly on the labor of their children. This may be one of the factors explaining the persistence of high fertility rates.

According to the 1979 census, 33 percent of all rural smallholder households in Kenya were headed by women, with the highest percentages in Nyanza, Eastern, Western and Central Provinces. Data from Kakamega and Machakos District show that even these high percentages do not fully represent the extent of *de facto* female-headed households. Surveys report that 55 and 47 percent, respectively, of the farms in these areas were in fact managed by women. Smallholder farm production is increasingly done by women. It is estimated that 96 percent of rural women work on the family farm; women provide three fourths of the labor on smallholdings and actually manage about two fifths of these smallholdings (World Bank, 1989b).

5.3 Efforts to intensify agriculture, conserve natural resources and reduce population growth will therefore have to be focussed to a significant extent on women. These efforts will have to aim, *inter alia*, at: reducing women's severe time constraints; lowering the barriers to women's access to land, credit and extension advice; introducing technologies useable by and beneficial to women; and upgrading women's educational standards and skills.

¹ Coupled with their often inferior health, nutritional and educational status, these pressures also render women poorly equipped to take advantage of emerging and better income earning opportunities outside agriculture.

B. The Female-Headed Household Syndrome

5.4 Female-headed households (FHHs) are a widespread and increasing phenomenon in many parts of Sub-Saharan Africa. It has always been common in societies which practice polygamy and spousal separation of residences, or where divorce has been fairly easy and frequent. In some regions, where long-term or seasonal male outmigration is particularly prevalent,² FHHs account for 50 percent and more of total rural households. This also means that an increasingly larger number of smallholder farms are managed by women.

A village survey in central Kenya found husbands absent in 70 percent of the households surveyed and the wives cultivating the entire holding. In the other 30 percent the wife cultivated her own plot within the holding. In the majority of cases, cropping decisions and input purchase and use were done by the women. Only credit decisions were taken by the husbands or by both spouses jointly (Due, 1988).

5.5 The concept of the female-headed household is often misunderstood and/or misinterpreted. It is not a static concept, but a life-cycle issue. African women may move in and out of being household head several times in the course of their lives (due to marriage, divorce, husband's death, remarriage, husband's outmigration, husband's return). Female-headed households are not simply a marginal group -- remnants of "nuclear families" that have lost their male heads due to death, divorce or migration. They are a common and economically and socially important reality. The vast majority of women in Sub-Saharan Africa who reach adulthood are likely at one or more times throughout their adult lives to be heading a household that is without a resident adult male. This is a reality with far-reaching implications for development policy, but one that is rarely recognized. An important policy implication is, therefore, that all women must be reached with development assistance interventions -- since they all are likely at some time(s) during their adult lives to be household heads when they will have to manage without the support of an adult male.

5.6 Female-headed households differ from male-headed households most importantly in that most of the former lack ready access to adult male labor. They are usually also underendowed in other important respects -- notably in land, capital, farm equipment, and transport aids. Land farmed may be far less than land allocated or controlled, due to the labor constraint and the lack of access to draft animals, farm machinery and hired labor. Capital may or may not be a constraint, depending on the incidence, amount and timing of remittances from absent husbands or other relatives.³ For most female-headed households, access to most public sector support services tends to be severely limited. This is especially notable in the case of extension, credit and services delivered through formal cooperatives.

Male-headed households (MHHs) in Zambia's Lusaka Province are far more likely than female-headed households (FHHs) to own oxen; hence, the farm area that can be cultivated is larger in MHHs. Male-headed households also have better access to other support services. In the Western Province, MHHs are six times as likely to have oxen than FHHs. The introduction of oxen into subsistence farming and of cash earning opportunities have both essentially been limited to men, leading to significant differences between male- and female-headed households -- a "feminization of poverty" (Sutherland, 1988).

² In Lesotho, about 60 percent of all males aged 20 to 44 are employed in South African mines (Plath *et al.*, 1987).

³ Men's remittances are often small, since they themselves are poorly remunerated, have to pay for their own food and lodging, may have taken a second wife, or prefer to retain their savings for major purchases of their own. Remittances tend to be used to purchase essential food supplies. Sometimes they are used to buy fertilizers and hire labor. Only rarely are remittances sufficient to permit investment in labor-saving machinery or livestock.

C. The Gender Division of Rural Labor and Farming Systems

5.7 Women are variously estimated to provide between 50 and 80 percent of all agricultural and agro-processing labor in most countries of Sub-Saharan Africa – prompting Ester Boserup to write of Africa as "the region of female farming par excellence" (Boserup, 1970). The gender division of labor (in farm and non-farm production, processing, marketing, household maintenance, subsistence and survival activities, child rearing, etc.), its determinants, and changes

In Malawi, agricultural tasks are assigned by gender and are sensitive to seasonal variation. A 1970 ILO estimate reported 40 percent of the agricultural labor force to be women; but the 1972 Census, with a one-week reference period, reported only 12 percent of the labor force to be female. The 1977 Census, using a one-year reference period, reported 51.6 percent of the agricultural labor force to be women (Doornbos *et al.*, 1988).

over time are important for agricultural and poverty alleviation policies. This division of labor varies widely among cultures. It is also determined by characteristics of the household,⁴ the individual, the farming system, the local natural resource base, the community, and the national economic and political system. Gender roles and responsibilities may undergo seasonal variations, due to farm production requirements, for example, or to seasonal male out-migration (Dixon-Mueller, 1985, pp. 119-123). Gender roles in farming systems also change over time, in response to cultural, technological, political, commercial, ecological, demographic and other factors.

5.8 Gender divisions of labor have implications, for instance, as regards the promotion of various crops, subsidization of certain inputs, targeting of research and extension, pricing, land tenure policies, etc. Shifts in cropping patterns will have different effects on labor required by genders. Control over returns affects incentives to work. Social norms need to be ascertained and considered to avoid mistakes. Three fifths of respondents to a survey in Botswana considered selling crops (but not cattle) a job for women only; extension, credit, transport and marketing interventions for crops would therefore need to focus on women to make sense (Dixon-Mueller, 1985). In the Eastern Uluguru Mountains of Tanzania, male involvement in such activities as fetching water and fuelwood or preparing meals is completely taboo (Mtoi, 1988, p. 349); efforts to address the water and fuelwood problems in this region would therefore need to be directed at women.

In Tanzania, awareness of female involvement in farming was extremely poor among officials and researchers – despite widespread visible evidence to the contrary. Farming systems research in Kilosa showed women contributing about half the labor on major crops and more than that on minor crops and on all other household tasks. Women were particularly active in planting (56%), weeding/thinning (52%) and harvesting (58%), but also contributed significantly to activities often assumed to be strictly male domains, such as land preparation (46%). Women's labor input was particularly high in rice (67%) and beans (59%), followed by maize (48%), sorghum (40%), sunflower (39%) and cotton (39%). Men dominated the marketing of all crops, except rice where women's contribution was 50%.

In a bean growing area of northern Malawi, women contributed 43% to total labor input in farming, 73% to domestic activities (excluding child care) and 43% to other economic activities such as trading, purchasing, beer brewing, etc.

5.9 The organization of farm labor and production responsibilities varies widely, but tends to be highly gender-specific. In some regions, men and women farm fields jointly, usually in a

In Zambia, women in male-headed farm households were found, to the astonishment of male researchers at the University of Zambia, to contribute more hours daily than the men to farm work (8.5 hrs vs. 7.4 hrs) as well as to non-agricultural tasks (5.0 hrs vs. 1.1 hrs) (Due, 1988).

⁴ Household size; gender and age composition; resource endowment; differential gender access to resources, services, equipment, credit, information, employment, markets, etc.

In southern Ghana, men used to clear land and fell trees; women planted, weeded, harvested, transported and processed the crops. With the introduction of coconuts, men moved into pure cash cropping, leaving food crop cultivation for home consumption entirely to women. Without male help, women often could no longer grow yams, the traditional staple, and switched to cassava which requires less labor and can be left in the ground for up to two years to be harvested when needed, but is also less nutritious. Today, most women grow plantains, maize, cocoyam, cassava, and vegetables; they also help the men, especially in headloading farm produce (Day, 1984b; Date-Bah, 1985, pp. 214-216).

In Zambia's Luapula Province, the gender-based labor division in farming varies with the farming system. In semi-permanent fields, men prepare mounds for cassava and ridges for maize; women plant, weed and harvest. In *chitemene* fields, men (usually sons-in-law) lop branches, while women pile and burn them, seed and harvest. Men dominate decision making for cash crops, women are responsible for food crops (Sutherland, 1988).

gender-sequential mode, but sometimes side by side. In other areas, a substantial portion of agricultural activities is gender-segregated: women grow their own crops on separate plots – but they are also required to work on the plots/crops owned/managed by their husbands. In much of Sub-Saharan Africa, men and women farm separate fields and grow different crops. Labor may be allocated by crop and/or by task – men performing certain tasks on women's fields and women certain others on men's fields. In some areas, men may work fields communally with other men, or gender-based work parties carry out certain tasks jointly. Hired labor is important in some areas and for certain activities. Labor sharing is common in some regions, usually within lineages or communities and often along gender-specific lines. The introduction of commercial crops (which may be food crops

intended for commercial marketing) or the commercialization of traditional crops often leads to changes in gender specificity of farming activities and responsibilities. Men tend to take on the market-oriented production, leaving women to cope with providing for the family's subsistence needs.

5.10 The gender-specific separation of farming responsibilities, with men and women producing different crops on separate plots, is often so explicit that there are two distinct gender-specific farming systems operating side by side. Details vary considerably among regions and socio-cultural groups, but in most of these dualistic systems, and where markets have developed for farm products, women tend to be responsible for the production of food crops for home consumption, while men more often produce explicitly for the market. This has often been couched in the simple dichotomy: cash crops = men's crops, food crops = women's crops. In this extreme simplicity, this statement is clearly not valid.⁵ Although industrial and export crops tend to be the domain of men, men also engage in substantial food production where food crops have good markets or where custom places the responsibility for producing the main staple on men. Where farming is generally subsistence oriented, men often produce the main staple on their fields (usually with considerable labor input from the women), while women grow a variety of supplemental food crops. Conversely, women do not necessarily limit their production activities to subsistence crops. Where market outlets exist and social customs permit, they not only sell part of their surplus (even if it is a temporary one and they have to purchase supplies in the market when the quantity stored at home is depleted), but they also produce a variety of "minor" crops for sale to pay for other household necessities.

5.11 The male and female farming systems differ in many important respects. They have different primary objectives and distinctly different resource endowments. They face different incentive systems and different constraints. Risk perceptions and risk management strategies differ

⁵ Among the Gulmantche in northern Burkina Faso, men traditionally cultivated and controlled the millet and cotton crops. When groundnuts were introduced as a cash crop in the 1940s to facilitate payment of taxes, women became the major producers of this crop. Men only began to take up groundnut cultivation in the 1970s when cotton cultivation became less remunerative (Hemmings-Gapihan, 1982).

Women's Rights to Land in Traditional Resource Systems

In **Ghana**, there are differences among ethnic groups. In most southern groups, land belongs to the lineage ("stool"). Any member of the lineage, male or female, is entitled to occupy unappropriated communal land and thereby acquire an interest (usufructuary title) in that land which for most practical purposes comes close to ownership. In practice, lineage members wishing to obtain land ask the lineage head to assign them a piece of land. It is widely claimed that there is discrimination against women in this allocation process: fewer women obtain land; women often get less fertile and than men; and women get smaller parcels. On low-fertility land, women can only grow cassava, and with smaller holdings they cannot practice shifting cultivation and must farm the same plot every year. Some women therefore also farm on land they receive as gifts from their parents or husbands. Among some patrilineal groups, such as the Krobo, women usually have no access to lineage land, except some unmarried women living in their father's home and farming land given to them by their father. With commercialization and cash cropping, land commercialization has occurred and land sales are now taking place, greatly eroding the principle of inalienable lineage landholdings. Tenancies have emerged as the other major form of rural land alienation (Date-Bah, 1985, pp. 221-222).

In **Kenya**, women traditionally did not inherit land, but their rights to use land belonging to a male relative were assured. Today, unless the land is registered in their own name, women's rights to the use of land are threatened by land commercialization. Except in some areas with matrilineal traditions, women make up only a minuscule percentage of registered land holders. Property rights after divorce or husband's death differ considerably among tribes, and customary laws are held up in courts. Among the Luo, Kisii and Masai, widows or divorced women may have to return to their native families, because wives have no property of their own. Kikuyu women are entitled to property acquired before marriage and to some share of property acquired with joint effort during marriage (Ventura-Dias, 1985, pp. 172-173).

In the rice farming systems of **Madagascar**, the household is the basic unit of production and consumption and the rice crop is the property of the household unit, but men and women have differential access to resources and complementary labor roles. Traditionally, men controlled the usufruct rights to most land. These were inherited by their sons; daughters could inherit land where there was enough. With increasing land pressure, control over land has become tighter and more individualized, with rights akin to ownership although these may not be officially registered. Women therefore do not generally have independent access to land, but grow household food and cash crops on their husbands' land. However, there are four ways in which a woman may acquire ownership of, or usufruct rights to, land on her own: a woman may purchase land; on divorce a woman has the right to a third of any land bought during the marriage by the household (even though the husband may have controlled the money and negotiated the purchase); widows may use their young sons' land to provide for raising their children; and widows and divorcees sometimes farm on a sharecropping basis (Dey, 1984b).

In the matrilineal-matrilocal communities in **Malawi's** Zomba district, women's tenurial security is very high, while that of men is low. Women tend to live in the settlements of their birth and obtain plots for cultivation either from their mothers or grandmothers or from the village headman (who has the formal right to allocate and reallocate land, a right increasingly rendered mute by the non-availability of vacant land). Women do not lose their land in the event of divorce, separation or widowhood (Hirschmann and Vaughan, 1983, p. 89).

Land ownership in **Sierra Leone** is communal. Women have access to communal land, but clearing and ploughing are too difficult for women who cannot afford hiring tractors or wage labor to do this. They therefore work mainly on land owned by their husbands or other male kin or as laborers on other farms for payment in cash or kind. Men and women cooperate in farming: women are mainly active in planting, weeding and harvesting, men in land clearing and tilling. Women also have home gardens or grow groundnut and cassava on abandoned rice fields for home consumption; surplus production is sold. They sometimes grow cotton which they spin, the men selling or weaving the yarn for themselves or the women. Rice is the main staple, and rice processing is female work (Stevens, 1985, pp. 285-286).

significantly, as do access to factor and product markets, to improved technology, to information, and to various support services. There also are important resource and commodity flows between the two systems. In most cases, the direction of these flows tends to be heavily biased in favor of the male systems. These factors all have implications for women's productivity, time and resource use, status and fertility decisions as well as for household-level food security and child welfare.

5.12 A major difference between the two farming systems concerns access to land. Where women have specific and gender-segregated crop production responsibilities (as distinct from

participation in farming activities controlled by men), this requires access to specific and distinct plots, and women's rights to land assume special importance. Although there are a number of exceptions, particularly in matrilineal communities with matrilineal residence systems, women's tenurial security is usually far less certain than that of men. Moreover, as men expand the scale of their farm operations in response to market incentives and by making more use of improved technology, they often reserve the better land for themselves, pushing women to more marginal land. Krou women living near the Tai Forest in Côte d'Ivoire had to leave their own fields because of expanding coconut and oil palm plantations and increasing immigration of new settlers from the Sahel. They were forced to move into the forest where they farmed clearings left by loggers.

In these areas, farming caused environmental damage and soils were not suitable for the cultivation of annual crops (Bamba, 1985).

In a village study in Cameroon, men were found to work an average of 32 hours per week, women over 64 hrs/wk. Domestic tasks took up 31 hrs/wk for women, 4 hrs/wk for men. Farm work averaged 12 hrs/wk for men and 26 hrs/wk for women. Men worked mainly on cocoa, but some also produced bananas and plantains for sale. Women produced mostly food crops, for home consumption and for sale -- food sales being their main source of cash income. Men engaged in a far wider range of non-farming activities than women, although trading in food, drinks and cigarettes was a frequent secondary activity for women. Men's hourly returns from non-farm activities were considerably higher than women's hourly returns from food crop production. Men helped their wives with some land clearing activities; women had to work on their husbands' plots when they were asked to do so.

When a road was opened through their village, women responded by more than doubling their time spent on growing food crops for marketing. Men responded by growing more bananas and plantains for sale to wholesalers and spending less time helping their wives grow food crops (Henn, 1985).

5.13 Access to labor is another problem. Women's farming systems depend very heavily on female and child labor. Adult male labor may be available from husbands or other male relatives, but usually only for very limited and specific tasks. In most settings, women's only resource is their own labor and that of their children to meet their production obligations in the face of multiple other demands on their time.⁶ This may contribute to the maintenance of high fertility rates. For female-headed households, limited access to male labor is a particularly severe constraint. A serious consequence of the decline in available male labor can be observed in many forest- and bush-fallow cultivation systems. In Côte d'Ivoire, for instance, men are often late carrying out their traditional tasks of clearing, burning and fencing women's upland rice fields; this results in late planting and reduced yields (Dey, 1984b). In some countries, lack of male labor for clearing dense vegetation and women's inability to do it with the simple hand tools available to them is forcing women to continue cropping land that needs fallowing to recover. Since women can clear light secondary bush, fallow periods are also being reduced (Dey, 1984b). In both cases, the result is more rapid degradation of such plots.

A project among the Tiv in central Nigeria assumed the operation of a joint-family farm -- although men and women traditionally have distinct labor roles and control of specific crops (men control millet, rice, benniseed and melons, women yam, cassava, maize, sorghum and cowpeas). Intended to increase productivity for all food and cash crops, the project had an uneven impact on male and female labor. Annual agricultural labor input increased by 17 percent for women, compared with 6 percent for men. Moreover, male labor requirements were distributed more evenly throughout the year, while much of the additional need for female labor was concentrated in October-December, adding a new major labor bottleneck. The gender-specificity of farming responsibilities and income control also meant that serious conflicts arose for both men and women at times of peak labor demand -- tradeoffs having to be considered between working on one's own crops or on those controlled by the other gender (Burfisher and Horenstein, 1985).

⁶ In many communities, women try to ease their peak labor constraints by participating in various forms of kinship- or community-based work group and labor exchange arrangements.

The Balanta Brassa in Guinea-Bissau

The farming system of the Balanta Brassa, the single largest ethnic group in Guinea-Bissau, is based on intensive irrigated rice cultivation in salt water *bolanhas* (swamp paddies), supplemented with upland cultivation of such crops as millet, sorghum, fonio, maize, cassava, groundnuts, beans, and upland rice. Fruit trees are also cultivated on upland areas, especially cashew. Rice is their main staple, and the men are responsible for providing it. Women are obliged to provide labor on their husbands' *bolanhas* as well as for furnishing the ingredients (vegetables, milk, fish, etc.) for the sauce that is eaten with the rice. Cattle are important to the Balanta Brassa, and both men and women can own cattle, but women more frequently own small livestock. Cattle are managed by boys and young men. Milk and dung are hardly utilized, cattle being primarily used to store wealth and for ritual purposes and social exchanges.

Land is collectively owned by the patrilineage, and the male head of the lineage allocates land to the compounds. The male compound head in turn determines the allocation of this land to collective as well as individual uses. Men have both collective and individual *bolanhas* and control the product from both. They also control most of the upland fields (*lugars*) which they prepare and seed, with the women helping with weeding and harvesting. Men undertake all the land preparation activities on fields intended for subsistence crops. Twice a year, they prepare the *bolanhas*, utilizing male age-group work teams if they can afford to feed and pay them (in kind and/or cash). Young men, usually in work groups, clear all new land for cultivation and build the ridges. They also ridge the *lugars*. Repair and maintenance of irrigation dikes and canals, regulating the water flow, and desalinating the *bolanhas* with rainwater is done by adult males, usually in work groups. Rice nurseries are prepared by each individual family, the men preparing the land, the women doing the seeding. Women are responsible for seedling transplanting (although men often help), weeding (men and particularly children will help), winnowing the threshed rice, and transporting it to the storage houses in the village. Rice harvesting and threshing is done by younger men in work groups.

Most men give their wives separate small *bolanhas* in the drier fringes of the swamps as well as *lugars* to grow a few crops of their own. The women cultivate their individual *bolanhas* and *lugars* on their own, usually by hoeing, with the help of their daughters and/or foster daughters. For ridging a groundnut field, they may obtain the help of their husband or hire a work group by providing rice and other compensation for them. Women also have their gardens in or near the village to grow vegetables.

The rice produced on the husband's *bolanhas* is owned by him, but the bulk of it is consumed by the family. Parts of it are given by the man in compensation for labor provided to his wives (for sale), parts are exchanged for tobacco or other consumer goods during the year, and any surplus is used to invest in livestock, preferably cattle. By contrast, crops produced on the women's fields and in their gardens are their personal property and may be sold by them.

With the increasing outmigration of males for urban employment, women are faced with greater direct responsibility for *bolanha* cultivation, but increasingly lack access to sufficient adult male labor to maintain these systems. Changes in hydrology, caused by prolonged drought and by upstream dam construction, are causing increasing salinity in the *bolanhas*, with significant negative effects on productivity. As a result of these developments, the pressure on upland areas for increasing cultivation is rising, with negative consequences for the environment and the sustainability of the traditional farming systems. Women are expanding their involvement in the production of palm oil and wine, are increasing their vegetable production for commercial sale as well as their commercial fishing and fish processing activities.

Balanta Brassa women are active in various artisanal activities: the production of ceramics, soap, palm oil and wine, salt, dried, salted and smoked fish. They also collect cashew nuts for sale and produce cashew wine for the market. They fish for shrimp and small fish and collect molluscs. Women also derive income from trading and from the sale of cashew wine, palm oil, processed fish, vegetables and rice.

Husbands' and wives' incomes are not pooled, and women have the legal right to dispose of their income as they please. It is not unusual for women to have more disposable income than their husbands. Husbands have full responsibility for the survival of the family and, except in times of abundance, all of the products from the male fields are kept for home use. Women's contribution is, thus, completely met through their labor on male fields. Women use their income primarily for their own and their children's personal needs, to compensate work parties, and to pay for ceremonies (Lifton, 1991).

5.14 Another example is the rapid deterioration of the natural resource base in parts of Zambia where *chitemene* farming is the traditionally predominant form of land use and where adult male labor is increasingly scarce at the farm level. With mainly women, old people and children as sources of labor, the traditional practice of climbing trees and lopping branches for burning on *chitemene* fields is being replaced by the felling of whole trees. This severely affects the regeneration capability of the available and accessible resource base (Vedeld, 1983, pp. 98-99). Moreover, the long distances between village and fields and the rising pressure on women's time are forcing people to shorten drastically the regeneration (fallow) period on their fields, cutting it from the traditional 25 years to as little as ten years (Stølen, 1983, pp. 32-33).⁷

In the *chitemene* farming system of the Bemba in Zambia's Northern Province, crops are grown on cleared forest plots fertilized with ash obtained by burning tree branches collected from an area five to eight times the size of the cultivated field. Millet, groundnuts and sorghum are grown for three years; then the plot is abandoned to regenerate. Men lop and fell trees and turn the soil. Men and women share in scaring birds away, harvesting and building storage facilities. Women turn the soil, plant, weed, scare birds, harvest and carry the produce home. They also cultivate pumpkins, sweet potatoes and groundnuts. Men hunt, fish and engage in inter-regional trade. Male outmigration became significant during the colonial era and caused gradual changes in the farming system. Since women could not easily lop trees, ash fertilization was reduced; where they tried to maintain the system, they cut down entire trees, but this inhibited regeneration. Cassava was introduced in the 1930s after a locust attack had caused severe food shortages. Traditionally, women had access to land, but with the rising emphasis on cash cropping of maize, cotton, sunflower, tobacco and groundnuts, men increasingly used the better land themselves and became less willing to allot good land to women for food cropping. Maize is eaten on the cob for a few months and is not significant in the diet; pounding meal takes too much time, and the crop is largely sold. Sweet potatoes are no longer grown in significant amounts. Neither is sorghum, due to the time consuming task of scaring birds away and the lack of suitable soils. Male outmigration continues and is significant. The use of oxen has helped make up for declining male labor availability, but does not reduce the time needed for sowing, weeding and harvesting which are women's tasks (Tembo and Phiri, 1988).

5.15 Since women more often lack the means to invest in agricultural intensification and soil conservation, farms managed by women are likely to be particularly constrained as regards possibilities for increasing productivity and particularly susceptible to resource degradation. Where farm machinery is available to the household or family, it is not necessarily available to the women; if it is,

then rarely at the critical time. Since women cannot afford to take any risk with the family's food security, they proceed instead with the traditional tools available to them, depending on their children (and sometimes other women in their village or kinship group) to provide the needed labor.

5.16 In most SSA farming systems, women also provide significant labor input on the men's fields. Polygamy allows men to command more labor (wives and children) and thereby extend farm size. Under most traditional tenure systems, land was/is assigned on the basis of ability to cultivate. Hence, more wives increase the capability to cultivate and the amount of land that can be controlled.⁸ As men expand their farming operations, their demands on women's labor (for planting, weeding, harvesting, crop transporting and processing) increase. Project interventions often exacerbate the problem. In a project in Cameroon, men received land, water, seed and training to produce rice; women were expected to carry out their traditional tasks in the men's rice fields in addition to cultivating sorghum for family subsistence (Dankelman and Davidson, 1988, p. 13).

⁷ Although millet is preferred in the diet in Zambia, cassava has increasingly replaced it as the main staple because millet production is constrained by the labor scarcity. Millet is now used mainly for brewing beer to generate cash income. Most people's *nshima* now consists of about 70 percent cassava meal and 30 percent millet meal; cassava meal is nutritionally considerably less valuable than millet meal.

⁸ Women often welcome an additional wife, because the husband is no longer solely dependent on a single wife and because a co-wife facilitates other methods of coping with survival needs.

A Wolof man in Senegal is responsible for providing his wife with decent housing and a bed, a hoe and sickle, new articles of clothing on the Islamic feast "Tabaski," the payment of taxes, and the main part of the bride-wealth of his sons. In addition, he buys the rope and the bucket for drawing water and salt. The woman is responsible for providing the herbs and relishes when it is her turn to cook, firewood, and the payment of about one sixth of the bride-wealth of her sons. She also buys the pulley for drawing water and medicines used by herself and her daughters.

A substantial part of household expenses is, thus, not borne by the women -- nor are new expenses always on the account of the women. For example, grain threshing is paid by the men, while grinding mills are paid for by the women. The cost of modern medicine is shared between husband and wife -- the women looking after themselves and the girls, the men looking after the boys. However, medicines used by the very young children are always bought by the women.

Nevertheless, women's household expenses are increasing. Due to population pressure, the area cultivated has increased and many useful trees and plants have disappeared or only grow far away from the village. Many women now buy herbs and relishes they formerly gathered in the forest. They also buy ingredients not formerly sold in the shops (e.g., dried fish, tomato paste, onions and sugar). Women now buy soap and matches (in former times soap was homemade, and the fire was left burning continuously). The Wolof woman also takes charge of purchasing household articles. Today, these are increasingly more numerous and include not only handicrafts, but also imported items such as plates and glasses. Even if these articles are initially bought with the husband's brideprice, it is the wife who pays for replacements.

The participation of men in paying household expenses is not only typical for the Wolof. Many Hausa men give their wives lamp oil, ointments, powder, perfume, and henna on religious or family feasts, or even every Friday; they also pay for the larger cooking utensils. Sharing of household expenses has also been reported for the Mandinga, Bambara and Fulani (Venema, 1986, pp. 90-91).

D. The Separation of Budgets

5.17 In most societies of Sub-Saharan Africa, men and women also maintain separate budgets, and there are intricate, but well established conventions concerning their respective sources of income and the responsibilities that are to be met from such income. Husbands and wives may sell to each other, even lend to each other at considerable interest rates. The support men are obliged to provide to their wives (and children) varies considerably among different communities. So does the importance of the immediate and extended family and of the household and compound as resource pools and as production and consumption units.

5.18 In most cases, women depend heavily on their own, independent (cash or kind) income sources, from farming and non-farm activities, to meet their responsibilities. This has crucial implications in terms of the incentives faced by men and by women with respect to investing labor and/or capital in specific farming activities or other ventures (including soil conservation or fuelwood production). Research from Kenya highlights this: "In female-headed households, weeding raised maize yields by 56 percent while in male-headed households, yields increased by only 15 percent. ... where women controlled the crop and the income from that crop, they did have the incentive to provide the necessary labor input for weeding which resulted in significant increases in yields" (Horenstein,

Among the Fula and Mandinga in Guinea-Bissau, men are responsible for ensuring an adequate supply of staple food for the family. The women are entitled to the produce and income from their own fields; they use it primarily to satisfy their own and their children's personal needs as well as to meet social obligations, but the husbands may take part of it. Among the Balanta Brassa, the men are responsible for filling the communal granary as well, women being required to provide labor to their husbands as well as the condiments that are eaten with the daily rice. Women, in fact, often have considerably more disposable income than the men, derived from farming and from artisanal and trading activities, and are free to decide upon its utilization. Papel women also have quite specific responsibilities concerning their financial and material contribution to household maintenance and consumption expenses. Husbands have some control over the utilization of their wives' income which is derived mainly from the sale of agricultural produce, fish, and cashew and palm wine (Lifton, 1991).

In the Mwea settlement scheme in Kenya, young (mostly nuclear, but sometimes polygamous) families were settled to cultivate irrigated rice. Rice fields were leased for life to male tenants, and small plots for growing traditional self-provisioning foods were lent to the household. This effectively meant that food plots were allocated to wives as long as they stayed with their husbands. In polygamous households each wife had use of such a plot. Although women were by tradition responsible for providing the family's food and had done so with small surpluses for sale from their food fields, the food plots in the new settlements were too small to ensure family food self-sufficiency. Planners simply assumed that part of the rice crop would go to family maintenance.

This led to serious difficulties. In addition to working their food plots, women shared in all rice cultivation tasks and did all the weeding – while the men had little to do on their rice fields between planting and harvesting and often left for several months. Many women, unhappy over their increased work load and the lack of control over the returns from their additional labor on husbands' fields, exercised passive resistance to work on the rice fields and did only minimal weeding, especially when this competed with work on their food plots. Although these plots were too small to supply the household with food, women wanted to work them as carefully as possible since they had full disposal rights over the produce. They also needed rice as well as cash to purchase additional food and other household necessities. They received some remuneration from their husbands, usually in the form of paddy, but this was insufficient; it was used to meet family food needs or sold to purchase preferred foods. This left them with inadequate cash to purchase firewood, a critical necessity since there were no forests nearby. A woman was considered fortunate if her husband bought six months' supply of firewood.

Community issues were discussed in tenant associations chaired by leading farmers appointed by project management – not appropriate fora for women to voice their complaints. Action was taken only when project management became concerned over the unexpectedly low rice yields and when some women took their complaints directly to management. It came in the form of better milk and firewood supplies, which ameliorated women's cash problems. It did not touch on the new and unfavorable set of intra-household exchange relations created by the scheme (Palmer, 1985a, p. 18; FAO, 1985, pp. 36-37).

1989, p. 13). Case studies abound documenting intra-family conflicts over the allocation of women's labor between crops considered to be under their own control as opposed to those being under the control of their husbands.

5.19 Given the separation of farming systems and budgets, the benefits of improved technology and productivity on male farming do not always translate into improved welfare for the women and children. Men often spend their additional income on further inputs for their own production activities or on personal consumption. It is not uncommon for children's nutrition to deteriorate while wrist watches, radios and bicycles are acquired by the adult male household members (M. Carr, 1985, p. 125). With women responsible primarily for family food and maintenance, men in fact often reduce their contribution to family and child maintenance costs (food, fuel, clothing, medical expenses, soap, etc.) as women's incomes rise (Henn, 1988). In the Banfora region of Burkina Faso (as among the Mandinga in The Gambia and Senegal), women spend a significantly higher proportion of their income on food, medicine, clothing and school fees for their children than do men. Men spend relatively large amounts for bicycles, beer or additional wives (Dey, 1984a, p. 64). A study of two villages in Malawi found that the nutritional status of women and children in particular was better in the subsistence village than in the village with significant cash-crop (tobacco) production. Although other factors might have played a role, women's greater labor input to tobacco production on men's fields contributed to lower subsistence food production and availability and reduced time available for cooking. Cash income generated from tobacco production was not used to purchase more food to compensate for lower subsistence production (Engberg *et al.*, 1988, pp. 99-100).

5.20 Where men and women have clearly defined complementary roles for providing for the family, the man often has no obligation to take over any of his wives' responsibilities even when they may have become unable to fulfil these themselves. If women lose their independent income, due to changes in farming systems induced by development projects or market forces, they may not be

Women, Food Security and Nutrition

Nutrition is a function of a number of factors, including not only food availability, but also suboptimal food preparation and feeding practices, pressures on women's time, lack of essential micronutrients, and poor sanitation and water supplies. The way mothers feed children and treat diarrhea also matters, as does the manner in which household income is controlled and spent or the selection and preparation of food. These behaviors appear to be independent of income levels and are compounded by poor health. Until progress is made in lowering birthrates and increasing food availability, efforts to improve nutrition must focus primarily on family-centered interventions to modify feeding practices. Nutritional status can be improved at any level of food availability. Women are obviously the main audience for nutrition education programs, especially as concerns the value of breastfeeding and young children's needs at weaning and beyond.

Food insecurity and malnutrition are, in large part, also a gender and generational issue. Even within the groups that suffer malnutrition most frequently (urban poor, landless laborers, subsistence farmers, nomadic populations), women and children tend to be most affected: "... within households, women get less food than men in absolute terms as well as in terms of their own nutritional requirements" (Horenstein, 1989, p. 14, citing McGuire and Pepkin, 1983). Small children and lactating mothers are the most vulnerable groups, and malnutrition is probably the biggest single contributor to high child mortality.

At the household level, food security is directly influenced by agricultural performance. Many of those facing food insecurity are small farmers -- often women -- in isolated areas with high transport costs and little or no access to markets. In most of these cases, increased production of food and greater stability in availability are likely to be the only ways to provide food security. Women face multiple constraints in securing adequate food for their children and themselves. Foremost among them are those rooted in the gender separation of farming and family maintenance responsibilities noted above. This highlights the need to redress the biases against women farmers in access to credit, extension, and research and development. Reforms in rural credit policies and institutions to promote female access to credit would help increase women's productivity in agriculture and their income from trade. In addition, the increasing fuelwood scarcity is having an effect on food preparation and feeding practices, with particularly serious consequences for small children. So are the difficulties women face in obtaining adequate quantities of safe potable water (see paras. 9.12-9.15).

Technology improvements are needed for processing and storing local foods. Shorter preparation time will become increasingly valued as urbanization proceeds and as women face more demands on their time. Grain varieties amenable to central processing and easier to transport need to be developed. Improvements in storage would reduce physical losses and improve the regularity of food supplies to local markets.

able to meet their customary obligations. This is not only shameful and distressing to them, reducing their social status and respect, but the family, especially children, suffer: nutritional levels fall, cleanliness may be affected (women spend a relatively large proportion of their money on soap), clothing may be less than adequate, and school attendance may well decline (Dey, 1984a).

E. Farm Technology and Gender

5.21 The separation of budgets also affects women's access to technology. Women farmers often are, or perceive themselves to be, restricted to low technology farming because they cannot afford purchased inputs. Lack of collateral (e.g., of land title) is only one part of the problem. Ability -- real or perceived -- to service debt is the other. Risk aversion is often far stronger among women than men, partly because a woman usually bears prime, if not exclusive, responsibility for feeding and maintaining the children and herself.

5.22 Gender is an important aspect of the farm technology problem (non-adoption, slow adoption, low utilization). Technology transfer is frequently hindered when intra-household dynamics are not taken into account. In many cases, women will have to provide the labor or be involved in the decision as to whether to adopt the proposed new technology or not. Failure to understand these factors or to consider who receives the benefits and who bears the costs, who will pay for follow-up

maintenance costs and investments, can be fatal to efforts at introducing new technology. In Ghana, women were reluctant to switch to a new hybrid maize variety because it had an unpleasant taste, was hard to prepare, was less resistant to insects and drought, required different storage methods, and needed fertilizers which affected its taste (Dankelman and Davidson, 1988, p. 18).

5.23 Few of the farm technology improvements developed and introduced to date have been geared to, or even cognizant of, the needs and constraints of women. The provision of mechanized equipment, new seed varieties, fertilizers and herbicides has largely been linked to the introduction or expansion of industrial/export crop production and has, thus, mainly gone to men. Female farmers have benefitted little. In many cases, women have in fact been left worse off. The introduction of animal-drawn ploughs may help men farm more land and/or reduce the time needed for land preparation -- but it does not help the women who then have to plant, weed and harvest. In Sierra Leone, the introduction of tractors and ploughs eased men's work load in rice cultivation, but women's work load increased by 50 percent due to more weeding and harvesting (Dankelman and Davidson, 1988, p. 13). Women's time constraints and the low productivity of their labor are already critical constraints to production increases, both on their own and on their husbands' plots. Yet women have not, on any significant scale, gained access to technology which would increase their labor productivity.

In Zimbabwe, hybrid maize was introduced directly to women farmers and production has increased substantially. In contrast, a program in Tanzania to promote hybrid maize cultivation through extension and the distribution of subsidized seeds, fertilizers and pesticides to men encountered resistance from women farmers who predominate in foodcrop production because it increased their workload without concurrent control over the income. There was also some resistance among the women to the cultivation of pure stands of hybrid maize, since maize is traditionally intercropped with beans or cassava. The latter represent a valuable complement to maize, and their reduced importance in the farming system could have negative nutritional consequences (Dey, 1984a, pp. 54-55).

5.24 The adoption of animal draft power in Sub-Saharan Africa is usually motivated by the men's desire to reduce (male) labor requirements and/or increase the acreage cultivated. A major multi-country study found that the additional area tends to be used to produce market crops (such as cotton, groundnuts and rice), while the area under subsistence crops usually remains unaffected by the introduction of animal draft power on the farm (Pingali *et al.*, 1987, p. 101). This finding confirms, of course, that farming intensification and investments in technological advances are associated with commercialization and market access. It also confirms, however, the technological gap between male and female farming systems even within the same household. Men take up animal-powered ploughing and expand their cash crop acreage and production, while women remain stuck with hoe cultivation on their subsistence crop plots (and are often required to provide more labor on the men's fields as well).

In Nigeria, gari production from cassava involves a number of steps: peeling, washing, grating, bagging, pressing and fermentation, sieving and roasting. For a typical 125 kg bag of gari, 200 tubers are needed, and the total time required for processing averages over 50 hours. Peeling (30 hours) and roasting (13.6 hours) are the most time consuming tasks. With costs of Naira 24.5-30.1 per bag and gross revenues of N 31-37.6 per bag, net revenue per bag of gari ranged from N 3.24 to N 10.60 in 1981/82 -- equivalent to N 0.06-0.21 per hour of work. Women in the sample surveyed produced between 4 and 12 bags per year. Efforts to introduce mechanization into gari production have not been very successful. Widespread adoption is reported only for mechanical graters -- but they are all owned by men who could afford the investment. Women benefitted only by having the drudgery of manual grating reduced. Industrial gari processing has been overcapitalized and underutilized and has so far had negative returns (Adekanya, 1985).

5.25 Where farm machinery is available to the household or family, it is not necessarily available to the women -- and if it is, then rarely at the critical time. In Senegal, "farming equipment is used first in the fields of the household head, then on those of his younger brothers or sons, in

order of priority based on age. Finally, the women have use of the machinery. Thus, women who wait for the use of seeders and hoes are late in planting and weeding, significantly reducing their yields" (Loose, 1979). Since women cannot afford to take any risk in providing for the family's food, they often prefer to proceed with the traditional technology available to them, even when the household possesses improved technological means. Ownership of improved equipment or technology, thus, does not necessarily result in any time saving for women or in productivity improvement in women's farming activities. And, as noted above, improved technology and productivity in male farming do not necessarily improve the welfare of women and children in the household.

Some successful attempts at introducing improved technology for women in Ghana included a low-cost, high-productivity fish smoking oven that required only minor adjustments from traditional smoking methods, sun-drying racks for fish, and improved cassava processing and garri making technology. Cultural taboos prevented the adoption of some technologies: women's participation in weaving and the prohibition on women touching cattle among certain groups. Technologies accepted have generally been those that improved upon or upgraded traditional techniques -- because this tended to ensure social acceptability by not disrupting accustomed practices, tastes, beliefs and taboos. Other important aspects of successful technology projects for women have been the involvement of intended beneficiaries in the identification and development of improvements, and the propagation of improved technology within a package comprising group formation, training and credit (Date-Bah, 1985).

F. Women's Time Use and Productivity

5.26 It is axiomatic that overcoming agricultural stagnation and food insecurity in Sub-Saharan Africa hinges on increasing the productivity of farm labor in general and in the production of foodcrops in particular. In many parts of Sub-Saharan Africa, where subsistence agriculture is largely a female task and/or where male outmigration has led to significant feminization of farming, this means that strong emphasis must be placed on increasing the labor productivity of women. And while this, in many ways, will require the same kind of measures that improve the productivity of male labor, it also requires far greater sensitivity in policy, program and project design to the different constraints and incentives faced by the genders in rural production systems. Very little will be achieved in increasing rural women's labor productivity without taking into account (a) the exact modalities of their involvement in agricultural and agro-processing work and (b) the severe limitations imposed on such work by other time-consuming child rearing, household management and other survival tasks.

5.27 Rural women work not only in farming. In much of Sub-Saharan Africa, they dominate many of the rural non-farm activities that grow most rapidly as rural economies undergo structural transformation -- activities such as food processing and preparation, tailoring, trading and many services. They also hold major interest in many of the declining rural non-farm occupations -- basket making, mat making, ceramics and weaving. Women will therefore be key actors in the economic transition of Africa's rural economy. To facilitate their contribution to an accelerated rural transformation requires that governments and donors explicitly recognize their key role (Haggblade *et al.*, 1987).

5.28 Increased female productivity contributes to economic development. It helps increase aggregate productivity in the economy, reduces the incidence and the negative welfare outcomes of poverty, reduces fertility levels, and increases household demand for health and education services. Increasing the returns to female labor raises aggregate family income, but also women's control over that income and, hence, the share of total "family income" spent on food, health care and other basic needs. Increasing female productivity also increases the opportunity cost of child bearing and thereby the incentives for families to invest in women's health and education.

5.29 "The real rural energy crisis is women's time" (Tinker, 1987). The single most binding constraint to increasing female productivity in farming, and in other income earning activities, may well be their lack of time – or rather the inordinate amount of time they must spend every day with onerous, time-consuming low-productivity tasks that are essential for family maintenance and survival. Easing this constraint requires measures which reduce women's domestic work burden. The provision of water and woodfuel sources close to the home would be an important first step. Essential, too, is affordable and appropriate time-saving technology which would reduce the drudgery of food processing and preparation, water collection, and fuel fetching and preparation.

In Togo, men grow the staples sorghum and millet, women provide the vegetables, meat, seasoning and sauces. Deforestation has sharply reduced the number of dawa dawa trees from which women collect the seed and the wood for boiling them into a condiment important in their diet. Child malnutrition is widespread. This led to an innovative and successful farming and family health project in Togo, Mali and Ghana, supported by World Neighbors and Family Health Advisory Services. It used soybeans as the entry point, but differed from other soybean projects in that it introduced them as a legume for making sauces rather than as a cash crop. Hence, the men did not object when the women asked for small plots to grow soybeans. The project started small, with demonstration plots and cooking demonstrations, visits to villages growing soybeans and workshops in women's homes. Initially used as a substitute for the increasingly scarce dawa dawa seed, soybeans gradually also came to be used in other dishes and for a high-protein porridge for children (Gubbels and Iddi, 1986).

5.30 To promote productivity gains for women farmers, a variety of measures are needed; many of these, particularly those concerning agricultural extension services, are already being implemented in a number of countries (para. 8.58). Far less has been done so far in other important areas to help improve the productivity of Africa's female farming systems. Researchers need to be far more cognizant of women's heavy involvement and special needs, objectives and constraints; important aspects in this context are species characteristics and processing requirements for new varieties. Women's rights to land and access to credit are two more areas in need of attention.

5.31 Improved agricultural tools and equipment are essential to improve the productivity of rural women. Many small "appropriate technology" projects supported by voluntary agencies have successfully introduced simple yet effective devices that require little maintenance and are cheap and easy to use. Equipment for milling, shelling, dehusking, initial conditioning and processing of crops and conservation of seeds offers many benefits in terms of raising productivity and allowing farm women to spend more time on other tasks. Small carts, wheelbarrows and bicycles could substantially reduce the drudgery and time required to transport agricultural produce and inputs both on the farm and to markets. These innovations have been largely neglected outside programs and projects supported by NGOs. They deserve far more emphasis in research and extension programs as well as in endeavors to promote local artisanal and small-scale industry.⁹

Hand operated cornmills were introduced into Cameroon in 1958. By 1961, membership of the societies founded by women to own and operate the mills numbered 30,000. With the time thus saved, the women turned to a variety of community and individual projects. They dug roads to their villages so that trucks could take out their produce; they piped water from small streams into storage tanks to provide them with water in the dry season; and they built meeting houses in central locations where they could hold classes throughout the year. They learned how to look after their children, to cook and make soap, to read and write, and to do simple arithmetic. They fenced in their farms and set up cooperative shops. Above all, they learned how to improve their farming techniques. (Carr and Sandhu, 1987; citing E. D'Kelly, Aid and Self Help, Charles Knight, London, 1973.)

⁹ A Bank-supported transport project in Ghana is moving in this direction: it supports the local manufacture of bicycles, bicycle trailers and wheelbarrows and, working with local NGOs, their acquisition by local women under a hire-purchase system linked with a labor-intensive road construction and maintenance and tree planting program (World Bank, 1990c).

5.32 Policies that alleviate women's capital and labor constraints are more likely to help increase food production than policies designed to attract men into food cropping (Henn, 1988). Steps taken in Zimbabwe, for example, to improve women's access to services and production incentives helped increase small farm output from 6 percent of the national total in 1982 to over 40 percent by the mid-1980s; one such step was to stop requiring husbands' signatures on wives' credit papers (Due, 1988).

5.33 Programs for promoting women's development encounter few ethical difficulties, but there is little evidence of rapid change in the role and status of women. Projects combining the provision of information and education about family planning with other activities directed at women's development have been successful; but most are small-scale efforts. A far more broad-based and sustained approach is needed. Women's education and technical training should be given priority. Women's organizations should be fostered. And women's non-farm and entrepreneurial skills should be upgraded in order to diversify the sources of family income.

VI. A FRAMEWORK FOR ACTION

A. A Continental Perspective

6.1 Successfully addressing the problems discussed in the previous chapters will require simultaneous efforts in three areas: (i) significantly, and as quickly as possible, reducing the rate of population growth through efforts that bring down the TFR; (ii) changing farming systems and cultivation practices from extensive to intensive systems which incorporate adequate soil conservation and fertility management measures to ensure long-term sustainability; and (iii) improving natural resource management so as to ensure that the natural resource base and agro-ecological environment remain intact. Essential to the achievement of these objectives will be addressing the special problems faced by rural women and the emerging land tenure constraints.

(i) Some Basic Targets

6.2 These closely interlinked objectives can be expressed in a basic set of quantitative aggregate targets for each SSA country regarding desirable and achievable population growth rates, food consumption, agricultural growth and environmental resource conservation (see Table VI.II, pp. 68-69). Although they are, of necessity, only rough approximations, they illustrate the magnitude of the effort required – but also the payoff that will result if the challenge is successfully met.

6.3 To summarize, for Sub-Saharan Africa as a whole, agricultural production needs to grow at about 4 percent per annum during the period 1990-2020. This, given the present weight of agriculture in Sub-Saharan economies, is the rate required to achieve aggregate economic growth of at least the same rate. Daily per capita calorie intake should be increased from its present average level of about 2,027 to about 2,400 by the year 2010. The share of the population that is "food insecure" should be reduced from the present 25 percent to zero as rapidly as possible. Unfortunately, scrutiny of the various country situations suggests that it is more realistic to aim for a target reduction to 10 percent by the year 2010 and to 5 percent by 2020. For environmental reasons, the rate of deforestation needs to be sharply reduced, from the present average annual rate of 0.6 percent of the total remaining forest area to about 0.35 percent per year. Loss of remaining wilderness areas should also be minimized: as an indication, approximately 23 percent of Sub-Saharan Africa's total land area should be maintained as wilderness (compared with about 27 percent today). To preserve wilderness and forest areas, cropped land can only be increased from 7.0 percent of Sub-Saharan Africa's total land area at present to about 8.3 percent in 2020. The arithmetic of these indicative agricultural, food security and environmental objectives requires population growth to decline steadily from the present average annual rate of over 3.1 percent to 2.3 percent per annum in the third decade of the next century. This will require lowering the average TFR by 50 percent between today and the year 2020.

(ii) Accelerating Agricultural Growth

6.4 The first requirement is to achieve sustained agricultural growth (more precisely, growth of agricultural value added) of 4 percent per annum.¹ This would permit gradually improving food security and increasing rural incomes and foreign exchange earnings and savings. Slower agricultural

¹ This is the minimum target set in the World Bank's 1989 long-term perspective study for Sub-Saharan Africa (World Bank, 1989d).

growth would also compromise the minimum macro-economic growth targets for Sub-Saharan Africa. Case I in Table VI.I (p. 63) shows the staggering food import requirements if present population and agricultural growth trends were to continue. The food gap, even at the present low average per capita food consumption levels (about 202 kg/cap/year), would increase from 10 million tons maize equivalent at present to 24 million tons by the year 2000 and to 80 million tons twenty years later.

6.5 Without a reduction in aggregate population growth rates, even sustained food production gains of 4 percent annually would only represent an increase on a per capita basis of less than 1 percent per annum. Even with unchanged average consumption per capita, and with interregional food trade completely liberalized to allow intra-African food movement from surplus to deficit countries, aggregate food import requirements would therefore decline only slowly and would be eliminated entirely only in the year 2004 (Table VI.I, Case II).

6.6 Even in this scenario, average per capita availability of food would not increase. There would, thus, (in the absence of distributional changes) be no change in the percentage of those malnourished and facing food insecurity, but a substantial annual increase in their absolute number. More than one quarter of Sub-Saharan Africa's population were faced with food insecurity in 1980/81 (Table 10), and the available aggregate statistics suggest a possible deterioration in this situation during the past decade. A scenario of unchanged average per capita food availability would imply, therefore, that over a quarter of all people in Sub-Saharan Africa would still be facing food insecurity 30 years from now.

6.7 The importance of making rapid progress in reducing population growth becomes even more apparent, therefore, when the closely related objectives of improving nutritional standards and food security are taken into consideration. Average daily calorie intake should be increased from its present very low level of 2,027 calories per person to about 2,200 by the end of the century and to 2,400 (i.e., the current average for the world's low-income countries) by the year 2,010. This would imply raising per capita food availability from an average of 202 kg/year to about 232 kg/year over a 20-year period. Table VI.I, Case V, depicts this scenario. Since aggregate food consumption requirements would rise sharply, even sustained growth in food production averaging 4 percent per year and a steady decline in the rate of population growth to 2.3 percent per annum during the decade 2020-2030 (implying a continuous reduction, beginning immediately, of the TFR over the next four decades to half its present level), the food gap would remain at roughly its present level of about 10 million tons per annum until 2010 and would not be closed until about the year 2015. The potential food surplus which might gradually emerge thereafter under the assumption of static average calorie intake would presumably not materialize because consumption levels would increase above the 2,400 cal/cap/day level that typifies present average conditions in the developing world.

6.8 It is clear, then, that -- even with 4 percent annual growth in food production -- the important objective of bringing the percentage of the population subject to food insecurity down to zero over the next three decades cannot be achieved, at the aggregate level, unless fertility rates are reduced by 50 percent and the population growth rate is thereby lowered to about 2.3 percent per annum by the year 2025. In addition, this objective will not be attained unless the growth in agriculture is equitably distributed over the population, benefitting urban dwellers as well.

6.9 The technological change required to realize the agricultural growth target of 4 percent per annum will need to be land-saving for environmental reasons and labor-using in order to absorb the growing rural population. With capital also scarce, the technological change being promoted must be carefully matched to farmers' capacity to finance investments. Incremental capital use will not be inconsistent with the objective of environmental sustainability. The present labor scarcity in much

Are Annual Cereal Yield Increases of 3.5 Percent Achievable?

The statistical analysis of the determinants of cereal yields, summarized in the box on pp. 45-46, can be used to test the plausibility of these projections. According to the equation given there, increased labor use per ha, facilitated by the growth in the rural labor force of 2.0 percent per year, would lead to 0.7 percent annual growth in cereal yields. Annual rates of increase in fertilizer use of 15 percent (and increases in the use of other modern inputs associated with increased fertilizer consumption) would generate cereal yield increases of 1.5 percent per annum. An annual increase of 2 percent in primary school enrollments would lead to annual increases in cereal yields of 0.3 percent. And an end to deforestation (if not an actual increase in forested area) would at least eliminate this cause of declining crop yields. Together, this would give a total growth rate of cereal yields equal to 2.5 percent per year.

Other factors -- such as more countries adopting appropriate agricultural policy and continually improving policies in all countries, a steadily expanding reach of rural transport infrastructure, improvements in marketing arrangements, etc. -- would have to provide the additional stimulus needed to achieve the postulated 3.5 percent growth rate. This is a difficult, but not impossible challenge to meet.

of Sub-Saharan Africa at the farm and household level, one of the driving forces behind the high fertility rates, will ease over time with population growth -- rural-urban migration notwithstanding. More labor per unit of land will lead to intensification. But intensification also requires making labor more efficient by adding capital. Part of this will have to be private capital, for fertilizers, animal traction, better tools, and investments in land amelioration and conservation. Much of it, however, will need to be public capital for rural roads and markets, water supply, investment in education, etc.

- To minimize the need for bringing more land under cultivation, the productivity of land will have to increase very rapidly. Allowing for a continuing expansion in total cultivated area at a rate of about 0.5 percent per year (from about 150 million ha in 1987 to about 180 million ha in 2020),² land productivity will have to increase by 3.5 percent annually over the next 30 years. Realizing this will be an enormous challenge (see box).
- Were the rural labor force to continue to increase at an annual average rate of about 2.5 percent, meeting the target of 4 percent annual growth in agricultural production would require that labor productivity in agriculture increase by at least 1.6 percent annually. Indeed, since those entering the rural labor force in the coming 15 years have already been born, the decline in fertility rates included in this set of indicative targets will only have a significant impact on the growth of the rural labor force in the outer years of the time horizon used here. If the targets are achieved for a continuous reduction in the average TFR to 50 percent of its current level by the year 2030 and, hence, for an average rate of population growth of 2.8 percent between 1990 and 2030, and if the urban population were to increase at an average annual rate of 4.5 percent due to continuing rural-urban migration, the average annual growth of the agricultural labor force is more likely to be around 2 percent for the period as a whole (higher in the first two decades, substantially lower thereafter). Labor productivity would therefore need to increase steadily over time so as to average about 2 percent per annum. Given the very high proportion of female labor in the total for the agricultural sector, and given the low current productivity of female labor in farming, an appropriate emphasis on improving the productivity of female labor will pay significant dividends in this regard.

² Clearly, the expansion of the land frontier cannot be halted immediately; in any case, in some countries there still are sizeable tracts of potentially productive crop land as yet unutilized -- due partly to technological constraints at the farm level (e.g., heavy bottom soils that require ploughing and possibly drainage), partly to difficult access (lack of roads).

Table VI.I Sub-Saharan Africa: Population and Food Security, 1990-2020

Scenarios	1990	2000	2010	2020
Case I				
Population (millions with total fertility rate remaining at projected levels) a/	494	664	892	1200
Food production (million tons of maize equivalent at current trend growth rate of 2 percent a year)	90	110	134	163
Food consumption (million tons with unchanged average per capita consumption) b/	100	134	181	243
Food gap (million tons) c/	10	24	47	80
Case II				
Population (millions as in Case I) a/	494	664	892	1200
Food production (million tons at 4 percent annual growth)	90	133	197	292
Food requirement (million tons as in case I) b/	100	134	181	243
Food gap (million tons)	10	1	-16	-49
Case III				
Population (millions, with total fertility rate declining by 50 percent by 2030) d/	494	657	875	1169
Food production (million tons at 2 percent annual growth)	90	110	134	163
Food requirement (million tons) b/	100	133	177	237
Food gap (million tons)	10	23	43	74

Food gap (million tons) e/	10	0	-20	-55
Case V				
Population (with total fertility rate declining by 50 percent by 2030)	494	657	875	1169
Food production (million tons at 4 percent annual growth)	90	133	197	292
Food requirement (million tons, with rising per capita consumption) e/	100	144	210	280
Food gap (million tons)	10	11	13	-12

a. Population growth at 3.0 percent per annum, as per Table 2.

b. Average of 2027 calories per person per day.

c. Equals consumption requirement minus production; negative sign denotes production surplus. This equaled the cereal imports plus food aid in 1990.

d. Target.

e. Average per capita consumption rising to 2,200 calories per day by 2000 to 2,400 calories per day by 2010 and stabilizing at that level thereafter.

What Will It Take to Arrest Deforestation?

The statistical analysis (see the boxes on pp. 45-48) suggests that a reduction in the area cultivated per person at the projected rate of 2 percent per year will stimulate further deforestation at a rate of 1.2 percent of the remaining forest area per annum. Annual population growth of 2.8 percent will lead to deforestation at a rate of 1.5 percent per year. On the other hand, an increase in the intensity of fertilizer use of 15 percent per year will lead to a reduction in the rate of deforestation of 2.9 percent yearly. The aggregate effect would be an increase at a rate of 0.2 percent per year in land under trees. However, a policy environment conducive to agricultural growth will stimulate farmers to expand cultivation into areas currently forested. The effort to preserve existing forests and expand the area under trees will be lost, therefore, unless environmental action plans and land use plans are prepared and implemented which channel the expansion of farming away from forests and from areas that are to be reforested. The indicative targets shown in Table VI.II imply, more realistically, continued reductions in the forest and woodland areas, but at much slower rates than those recorded at present.

6.10 In the longer run, as the scope for policy improvement narrows, and with increasingly more stringent constraints on the possibilities for further expansion of cropped area, sustaining an agricultural growth rate of 4 percent per year will become even more difficult. It will depend increasingly on intensification through greater use of modern inputs and equipment, diversification into higher-value crops, genetic improvements in crops and livestock, and general improvements in educational attainment of the population. Hence the importance of the improved agricultural research, extension, and of general education discussed in subsequent chapters.

(iii) Managing Forest Resources

6.11 The growing population of Sub-Saharan Africa will need more fuelwood, building materials and other wood and non-wood forest products. Woodfuel demand will increase roughly at the rate of population growth.³ Demand for other wood products should probably increase more rapidly, to allow development of forest-based industries, especially rural industries. Although the implications of such rising demand on forest area requirements are very difficult to quantify for Sub-Saharan Africa as a whole, orders of magnitude can be delineated here.

6.12 In 1984-86, an estimated 370 million m³ of fuelwood and charcoal were extracted, much of it in a manner destructive to the forest resources, from Sub-Saharan Africa's forests and woodlands (World Bank, 1989d). This implies an average per capita consumption of about 0.87 m³ per year and is consistent with the average per capita consumption estimates of about 0.5 m³ per year in urban areas and about 1 m³ per year in rural areas. With about 100 million urban and 322 million rural dwellers in 1985, aggregate consumption, using these average parameters, would have been on the order of 372 million m³.

6.13 With aggregate population growth declining over the next four decades to a rate of 2.3 percent per annum (and, thus, averaging, about 2.8 percent per year over this period), Sub-Saharan Africa's total population in 2020 would be on the order of 1,169 million (Table 4). If urban population growth were to average 4.5 percent per annum (considerably less than in the last three decades), the urban population in 2020 would total about 485 million (up from about 130 million at present).⁴ The rural population would rise to about 685 million by 2020, implying an average rate

³ Efficiency gains in energy conversion/use and some interfuel substitution in urban areas will somewhat dampen the rate of demand growth, but meeting currently unmet demand in fuelwood-deficit regions would have the opposite effect.

⁴ Successfully addressing the problems discussed here would help reduce the rate of rural-urban migration.

of increase of a little over 2.1 percent per year. Properly managed fuelwood plantations may sustain yields, on average, of 4 m³ annually per ha in the savanna zones and about 10 m³/ha/year in the forest zones. It may be assumed that the urban population in 2020 will be about evenly distributed between these two main climatic zones. With average fuelwood requirements for urban dwellers amounting to 0.5 m³ per person per year (in view of gradually increasing interfuel substitution and improvements in fuel utilization efficiency), 30.3 million ha of fuelwood plantations would be needed in the savanna zones in 2020 and a further 12.1 million ha in the forest zones to meet urban woodfuel requirements entirely from managed plantations. Assuming a lag of ten years from planting to harvesting, these plantations would need to be established within the next two decades; this implies an annual rate of plantation establishment of more than 2.1 million ha every year, beginning immediately.⁵ Thereafter, further expansion in plantation acreage would need to match further growth in requirements (minus efficiency gains).⁶

6.14 Of course, much of the woodfuel for urban markets can and should come from managed forests, rather than plantations. Forests managed for sustainable woodfuel production could yield, say, an average of 1 m³/ha/year in the Sahelian and Sudanian savanna, about 2 m³/ha/year in the Guinea savanna areas and an average of 4 m³/ha/year in the forest zone. Using an average sustainable yield estimate of 1.5 m³/ha/year for forests in the savanna zones, 81 million ha of well managed forests in the savanna zones and 30 million ha in the forest zones could, theoretically, meet the woodfuel needs of the urban population in 2020. This would imply that about one fifth of Sub-Saharan Africa's entire remaining forest area would need to be brought under effective management regimes with the aim of providing an adequate flow of woodfuels for the urban population on a sustainable basis. Since almost half of the remaining forest area is concentrated in a few countries in the central African forest zone (Zaire, Gabon, Congo, Central African Republic, Cameroon) and on Madagascar, the proposition of meeting urban needs from managed forests in the other countries means, in fact, that a far greater proportion of the forest areas still remaining in these countries will need to be managed in a manner that would ensure sustainable woodfuel supply over the long run. This will be increasingly the case as forests and woodlands are converted to farmland and other uses.

6.15 Rural populations would need to meet their woodfuel needs increasingly through agro-forestry activities. Rural requirements may average about 1.0 m³ per person annually. If a ten-year old tree yields, at felling, 0.2 m³, this would indicate a need for 5 trees per person per year -- or 50 trees per person in a ten-year planting and harvesting cycle. For a ten-member household, about 500 trees would be needed -- around the compound, on field boundaries, in windbreaks, in alley-cropping systems, and in village groves and woodlots.

6.16 Clearly, these numbers can merely provide a rough indication of the orders of magnitude involved in satisfying woodfuel needs. As discussed earlier, the various dimensions of the fuelwood issue are highly location- and region-specific and require, thus, careful attention at the national, regional and local levels. Nevertheless, on balance, it is critical to bring about an immediate and drastic reduction in the rate of deforestation and to expand the area of productive managed forests, forest plantations and tree farming to meet the vast needs for woodfuels and other wood products. An attempt has been made to determine realistic targets for the major regions of Sub-Saharan Africa

⁵ To the extent that transport facilities can be improved and the switch from fuelwood to charcoal and briquettes can be accelerated, more productive plantations in forest zones could meet some of the needs of urban populations in savanna zones, thereby reducing the overall acreage needed for fuelwood production.

⁶ Many degraded and currently unproductive woodland areas could be reforested; hence, not all this acreage required for fuelwood production would need to be in addition to current forest and woodland areas.

for the area under trees. These are shown in Table VI.II. They reflect projected wood requirements, plantation and tree farming possibilities, and projections of required and feasible expansion in cropped area. Realism suggests that deforestation cannot be stopped entirely. But it should be possible to lower the overall rate of deforestation from the present 0.6 percent per year to 0.35 percent per annum. This means that the average annual rate of cropland expansion would have to be reduced from the present 0.7 percent to about 0.5 percent. These are realistic targets. But achieving them requires that forests used for wood production be managed efficiently, so that wood harvesting would suffice to meet the needs of populations growing at 2.8 percent per annum and also satisfy essential environmental objectives linked to the environmental service functions performed by trees and forests.

6.17 The challenge posed by these targets is enormous – requiring, as it does, a complete and rapid reversal of past trends rather than merely an intensification of ongoing efforts to accelerate along a growth path already attained. As indicated in the preceding chapters, the destruction of forest resources is the result of a variety of interlinked factors and forces. Achieving the target postulated here will be even more difficult than attaining that for agricultural production growth.

(iv) Conserving Wilderness Areas

6.18 To preserve biodiversity and the economic and social value of non-forest wilderness areas, these areas should not be allowed to decline very much from their present extent of about 27 percent of Sub-Saharan Africa's total land area. A reasonable target was derived by projecting forward the present rate of wilderness conversion to urban and infrastructure development and the postulated maximum expansion of cropped land (which also comes out of wilderness areas). This means that wilderness area would decline to about 23 percent of SSA's total land area (this compares with 39 percent of the world's land area currently classified as wilderness areas). This would allow a continuing modest expansion of cropland at an average annual rate of 0.5 percent over the next three decades and an expansion of urban land at about 7.9 percent per year as per current trends.

6.19 Achieving this objective of wilderness conservation will be as difficult as achieving that for reducing the rate of deforestation – and for the same reasons. One difference, however, is that education appears to be successful in creating heightened awareness of the value of wilderness areas. Improvements in the coverage and efficacy of basic education are therefore likely to help, as are agricultural intensification and reduced population growth. On the other hand, a policy environment conducive to agricultural development and growth will provide strong stimuli to farmers to encroach on wilderness areas in order to expand the area under cultivation (the effect is far stronger than in the case of deforestation, presumably because of the far greater ease of converting non-forested land to farming). This underscores the importance of: (a) land use plans and environmental action plans and of their effective implementation to prevent such a development, (b) effective policies and infrastructure development to channel cropland expansion into less sensitive areas, and (c) the urgent need to ensure widespread farmer access to markets and to yield-increasing farm technology.

(i) Summary

6.20 There are, of course, considerable country variations in what is necessary and attainable, and the above indicative overall targets have been adjusted to each country's circumstances and potential in Table VI.II (pp. 68-69). Nevertheless, these targets are extremely ambitious. They indicate the magnitude of the problems faced and the efforts required. The elements of an appropriate action plan outlined in the following chapters are, therefore, similarly ambitious. Reaching these targets will be possible only by focusing on the synergetic effects inherent in the linkages and causality chains of the population-agriculture-environment nexus. With rising agricultural

productivity and outputs and growing incomes, population growth rates are likely to decline more rapidly. With agricultural intensification and decelerating population growth, environmental protection and resource conservation become more feasible. And preserving environmental integrity makes it easier to achieve sustainable agricultural growth.

6.21 If the objectives set out in the preceding paragraphs are successfully attained, the vision of the future of Sub-Saharan Africa would be one with a more slowly growing population, and with the rural population increasing more slowly than the urban population. Significant gains in both land and labor productivity would permit the population to feed itself and to increase incomes, without expanding the area farmed beyond what is environmentally sustainable and without depleting the natural resource base. This would be accomplished by the widespread adoption of locally appropriate sustainable agricultural technology and resource management practices, increased land tenure security, and special efforts to improve rural women's productivity and ease their time constraints. Reducing the rate of forest loss and preserving a substantial part of Sub-Saharan Africa's wilderness areas would permit preservation of biodiversity and wildlife and ensure the lifestyles and survival of indigenous forest peoples. It would also ensure an adequate supply of fuelwood and wood for construction and local industry and of other forest products for consumption and income-generation purposes. These various interventions would have a positive synergistic effect -- as the negative effects of the present situation are synergistically related. Improved agricultural incomes (especially in conjunction with improved education and health care) would further induce declining family size, in turn reducing the pressure on the environment and allowing for some environmental regeneration. This in turn should have a positive impact on agriculture.

6.22 Realizing this vision will be enormously difficult, requiring radical changes in governmental policy and a strong commitment to assisting Sub-Saharan Africa on the part of international community. African governments, external aid agencies, and African and international NGOs will all need to pursue this goal. Most important will be the effort of millions of Africans acting, individually and collaboratively, in their own self-interest. The major elements of an action program are described in the following chapters.

E. Some Country-Specific Targets and Implications

6.23 Aggregate targets for Sub-Saharan Africa as a whole obviously are of limited operational relevance for individual countries. But they provide a useful and compelling framework within which appropriate objectives and targets will need to be set at the country level. Policy and public investment decisions are made at the country level. Table VI.II summarizes the present situation and sets out some internally consistent targets for each SSA country with respect to agricultural growth, calorie supply, food insecurity, population growth, deforestation, percentage of land under cultivation, and percentage of land remaining as wilderness areas. There are some trade-offs between growth of agriculture and environmental protection -- but these are far outweighed by substantial and positive complementarity. Nevertheless, the trade-offs require that choices be made -- and these can be made only by the people in the countries themselves. The targets in the table are therefore also indicative of the trade-offs.

6.24 There will be wide differences in the degree of difficulty various countries will experience in meeting the objectives. Some countries are already on course to meet some of the critical targets, but will need to do better in other respects. Others are faced with the necessity of drastic action in all areas concerned to attain a development path that suggests any likelihood of success in reaching the targets postulated here. Still others are likely to face virtually insurmountable obstacles in certain respects, and solutions that go beyond national boundaries will need to be seriously considered.

Table VI. II. Sub-Saharan Africa: Targets for Food Consumption, Agriculture, Population and the Rural Environment

Country	Annual agricultural production growth rates (percent)		Annual population growth rates (percent)		Daily per capita calorie consumption		Population food insecure ^a (percent)		Deforestation rates per year ^b (percent)		Total land under crops (percent)		Wilderness area to total area (percent)

a. Defined as percent who do not have adequate food all the time.

b. A negative number means deforestation as percent of total forested area per year.

c. Average annual rate for 2020-2030 if the target of reducing the total fertility rates to 30 percent of their current levels is achieved by 2030, see table 4.

Methodology used to develop these targets and projections

1. The target agricultural growth rates reflect what is necessary in the long term to contribute to the minimum 4 percent p.a. economic growth rate established in the World Bank's: Sub-Saharan Africa, from Crisis to Sustainable Growth, 1989. The targets require good agricultural policy and investment of the type described in the text, and are significantly, above projections. Present agricultural growth rates are shown in appendix Table 9.
2. The target population growth rates were established as discussed in appendix Table 4. They reflect the projected outcome in each country of the achievement of a reduction in the total fertility rate by almost 50 percent by 2030. Present growth rates: Table 2.
3. Minimum target calorie consumption was initially set for all countries to equal the present average in all the world's low-income countries; it was then adjusted upwards for those countries that already have comparatively high average levels of per capita calorie consumption and downwards for those with currently very low levels. Present levels of intake: Table 10.
4. The target percentage of the food-insecure population is based on a subjective judgment about the possibility of reducing food insecurity in each country given the present numbers involved, the target agricultural growth rate, and the available new land for cultivation. Present percentage: Table 10.
5. Reduction in deforestation is related to the tree cover to supply projected wood needs of populations growing on average at 2.8% p.a, with improved management, and also satisfying essential environmental objectives, while allowing for continued expansion of cropland (See paras 6.10-6.13). The source for these estimates is Mr. F. Wencelius, World Bank, Africa Technical Department, March 1992. Realistic targets, accommodating a minimum expansion in cropland, were set for each sub-region rather than each country. The results in millions of hectares of forest are as follows:

	<u>Year</u>	
	1990	2020
	<u>(millions ha.)</u>	
Sudano Sahel	90.0	75.4
Humid West Africa	43.0	38.6
Central Africa	215.0	192.4
East Africa	46.0	42.8
Southern Africa	<u>206.0</u>	<u>189.2</u>
Total	<u>600.0</u>	<u>538.4</u>

6. The target percentage of land under crops was determined on the basis of available wilderness, forest, and other uncultivated land for cultivation, given the constraint imposed by the need to reduce deforestation to the target rate for each country. For Sub-Saharan Africa as a whole, the target deforestation rate is 0.35% p.a. This amounts to a reduction of forested area by about 2.3 m.ha per year compared to the present 3.7 million p.a. But only about 30% of the land taken out of forests are cultivated, allowing about 650,000 ha. p.a. in expansion of cultivated area. This is equivalent to a 0.5% p.a. expansion in cultivated area for SSA as a whole. This would result in about 8.3% of SSA's land area put under crops by the year 2020. The amount of change would vary by sub-region since the rate of deforestation varies by sub-region; hence a similar calculation was undertaken for each country.
7. The minimum target wilderness area to be retained was arrived at as that remaining after taking out the postulated maximum increase in cropped land (1.3 percent expansion in total area by year 2020), and loss on account of urban, industrial and infrastructure development at its present rate of 5.8% increase every 22 years (table 15). The result is that wilderness loses 2.8% of total land to urban, and 1.3% to crops, hence declining by 41% of total land area, on average. A similar calculation was undertaken for each country.

6.25 Mauritius, for example, has already achieved the targets for population growth, calorie intake, and the percentage of its population facing food insecurity. It also has achieved modest agricultural growth, averaging about 2.6 percent per annum during the 1980s. At present, the rate of deforestation is high (3.3 percent p.a.), and the objective should be to reduce the rate of deforestation to about 0.3 percent per year. Crop land cannot be expanded on this island nation. This underscores the necessity for substantial effort at further agricultural intensification and/or economic diversification to meet rising needs for food and other agricultural products through international trade.

6.26 Ethiopia is at the other extreme. Adverse climatic conditions and prolonged civil strife have had a severe impact. Agricultural production has stagnated during the past decade, average daily food intake is a meager 1,684 calories per person, 46 percent of the population are food insecure, and forests are disappearing at a rate of 0.3 percent annually. At 2.9 percent per year, population growth is somewhat below the SSA average -- not so much because of declining fertility, but because of the high child mortality and overall death rates. The targets set out here for Ethiopia are more modest than those for most other countries, simply because of its critical situation. The area under cultivation will need to increase from 13 percent to 26 percent of the total land area by 2020 to meet the target of 4 percent annual growth in agriculture. Deforestation cannot be halted with this expansion of cropped land, but is in fact likely to accelerate, given the difficulty of intensifying agriculture in a dry environment.

6.27 Uganda provides yet another picture. Its agricultural performance has been poor, owing largely to civil strife, with some impressive improvements in recent years. Agricultural growth averaged 2.5 percent annually during the 1980s. Population growth has been rapid (3.2 percent per annum). Most of the arable land is already under cultivation (34 percent), and there is little wilderness area left (4 percent of total land). The rate of deforestation has averaged about 0.8 percent per annum recently. Uganda has enormous agricultural potential: its agricultural sector could grow at a sustained rate of 4.5 percent annually. If population growth can be reduced to 2.7 percent per annum by the year 2020, average daily calorie intake per person could rise from 2,034 to 2,400, and the number of people facing food insecurity could be brought down dramatically. This would have to occur mostly through intensification on currently cropped land, because there is little additional land left to cultivate. AIDS already is a more serious problem in Uganda than in many other African countries; this suggests that efforts to improve the reach and effectiveness of health care and family planning services are critical.

6.28 A number of countries are facing scenarios of extreme difficulties and constraints: Rwanda, Burundi, the Sahelian countries, Kenya and Malawi. The case of Rwanda is particularly dramatic. Agricultural performance has been poor, with production declining at an average rate of 1.5 percent per year in the 1980s. Population growth has averaged 3.3 percent per year during the 1980s. Per capita daily calorie consumption is only 1,817, and 24 percent of the people are food insecure. There is little wilderness left, although nearly 15 percent of the country has been set aside as protected areas. The rate of deforestation has been 2.3 percent per year, and 45 percent of the entire land area is cropped. The modest agricultural growth target of 3 percent per year can only be achieved through agricultural intensification. Population growth must be reduced to the maximum extent possible. The very high population density may be creating demand for smaller family size; FP interventions should seek to capitalize on this. Reforestation must be intensified, on land unsuitable for crops. The difficulties are immense. Indeed, the targets spelled out here imply that 19 percent of the population will still be food insecure in the year 2020. Out-migration to other countries will clearly be inevitable.

6.29 **Nigeria's** example is important, if only because of the country's size. It's agricultural performance during the 1980s has been marked by widely fluctuating production, with a trend growth rate of 3.3 percent per year, matching the population growth rate. The country has such potential for growth that, with appropriate policy reforms in key areas, it can achieve 4 percent agricultural growth per annum in the medium term. As much as four fifths of this growth can be realized without expanding the area under cultivation because of the availability of proven yield-increasing technology for several key crops and the scope for double-cropping through small-scale irrigation. The remainder will come from modest expansion of the area cropped. Realignment of public expenditure toward small-scale irrigation, provision and maintenance of rural roads, improvement in agricultural support services, reduction of the fertilizer subsidy and liberalization of fertilizer imports and marketing are key areas requiring policy reform. Without such reforms, future agricultural growth would have to come primarily from area expansion which would not be sustainable. The country's family planning effort, very weak at present, will have to improve considerably for the target population growth rate of 2.1 percent per annum to be reached by the year 2020. As population pressure on cultivated land is rising, demand for FP services appears to be increasing in parts of the country, and FP programs will need to foster such demand growth and meet this rising and largely unmet demand. Substantial policy reforms will be needed to stop the rapid destruction of existing forest resources and to induce sufficient private investment in agro-forestry, fuelwood and industrial plantations if the target of reducing deforestation to an annual rate of 0.3 percent is to be met.

VII. REDUCING POPULATION GROWTH

A. Population Policy

(i) Key Issues and Challenges

7.1 Chapter III suggested several avenues for reducing population growth. Fertility rates can be brought down by emphasizing direct actions such as improving knowledge and availability of family planning (FP) services. But to have maximum impact, these "supply-side" efforts need to be backed, if not preceded, by efforts to stimulate demand – such as improving education, especially of females, reducing infant mortality, improving food security, and reducing environmental degradation. Family planning education can be provided through FP services, along with the means to control fertility. By providing nutrition advice, FP services can also help in reducing infant mortality and improving nutritional standards. Increasing density of population on cultivable land may also stimulate demand for fewer children. Acceptance and adoption of FP will spread most rapidly in countries where demand for FP services is increasing fastest. This is likely to be in countries with the highest levels of female education, the lowest infant mortality, the highest population densities on cultivated land, the least environmental degradation, and the greatest food security.

7.2 Governments are increasingly aware of the consequences of rapid population growth. In 1974, only Botswana, Ghana, Kenya and Mauritius had adopted policies to reduce population growth. By 1987, 14 countries had adopted explicit national population policies (Cochrane, Sai and Nassim, 1990, p. 229), and a number of others have done so since then. In 1989, 26 governments in Sub-Saharan Africa considered their population growth rates, and 29 their TFRs, to be too high (Stephens *et al.*, 1991, p. xxxv). But few have so far provided adequate technical, financial and managerial resources to promote and deliver FP services broadly. Hence, progress has been slow.

7.3 Only a few countries on the continent – notably Botswana, Kenya and Zimbabwe – have been implementing population programs that have shown some measurable success (Tables 2 and 8). The Contraceptive Prevalence Rate (CPR) in Botswana more than doubled, from 16 percent to 33 percent, between 1984 and 1990, as FP services were placed within easy reach of the majority of the population. Botswana's TFR declined from 6.9 in 1965 to 4.7 in 1988. Kenya succeeded in raising the CPR from 5 percent in the mid-1970s to 17 percent in 1984 and to 27 percent in 1989, and the TFR declined from 8.0 in 1965 to 6.5 in 1989. In Zimbabwe, the CPR is now estimated at 43 percent, and the TFR dropped from 8.0 to 5.3 between 1965 and 1988; the creation of a network of FP clinics and of a community-based outreach program which widely distributed contraceptives was instrumental in providing access to FP services. An indication of changing attitudes concerning fertility and of growing demand for FP services is evident in the number of children desired by women in these three countries. In 1988/89, women wanted only 4.7, 4.4 and 4.9 children, respectively, in Botswana, Kenya and Zimbabwe – far fewer than their counterparts in other SSA countries and also far fewer than women in the same three countries only ten years ago (Table 8).

7.4 Government policies in these countries have played a major role in achieving fertility reduction through an expansion of FP services and education. However, in each of these countries the fundamental forces have also been working: relatively dense population on cultivated land, relatively high female school enrollments, good agricultural performance contributing to enhanced food security, and declining infant mortality. Yet even in these three relatively successful countries, the TFR must be brought down still further.

7.5 To lower the population growth rate to 2.3 percent per annum for Sub-Saharan Africa by the year 2030, the average TFR for Sub-Saharan Africa as a whole must drop steadily to 3.3 by that time (Table 4). This is possible, as shown by evidence from countries outside Africa where per capita incomes are low and populations largely rural, and where infant mortality rates and life expectancy, when the effort was initiated, were comparable to those in Sub-Saharan Africa today. It requires determined effort and commitment from the political leadership to shape public attitudes and implement policies and programs to reduce population growth.

7.6 Significant reductions in fertility cannot be expected until the CPR reaches 25-30 percent. Slowing population growth to only 2.3 percent per annum during the period 2020 to 2030 would require increasing the CPR substantially above even this level. This underscores the need for fostering greater awareness of the consequences of population growth as well as the need for measures to stimulate demand for FP services. Increasing the availability of FP services raises the level of their use. There is evidence that, even at the present levels of demand for family planning, the CPR in Sub-Saharan Africa could be raised to 25 percent within the current decade by making services widely, regularly and reliably available. It will require a rapid expansion of access to FP services, and this, in turn, will require strengthening and expanding public health care systems and developing multiple channels (public sector, private commercial, NGO, community organizations) for delivering services as well as information, education and communication (IEC). The progress achieved in Botswana, Kenya and Zimbabwe indicates what is possible, when the various other factors that bear upon demand for children also moving in the right direction (Table 8).

7.7 The ethical issues in family planning in Sub-Saharan Africa form a complex web of social, economic, cultural and developmental concerns, and dialogues on ethical issues in family planning is crucial if the process of 'depoliticizing' family planning is to continue (Sai and Newman, 1989). The promotion of family planning as a basic human right and as an important health measure has increased its acceptability, and family planning is now increasingly regarded a legitimate component of overall development efforts. But the "human right" to controlling one's own fertility remains elusive without full and ready access to FP information, education and services. This entails full and voluntary choice of method, right of access for young people, and financial affordability of fertility regulation services. Each of these has caused ethical controversy in some countries. The right of access to FP services is derived from the basic right to make decisions about reproductive behavior. This, too, has been controversial in some countries.

7.8 Family planning is also a major element of the rights of women. Many women prefer to have fewer children, but are discouraged from adopting family planning by socio-cultural factors, including their husbands' wishes. This highlights the importance of reaching men, either at the workplace or through other means such as the agricultural extension services. It also suggests that women's groups would be an effective channel for delivering family planning services because they foster solidarity among women and may help them take fertility decisions on their own.

7.9 In about a dozen countries, fertility regulation programs are part of national population policies.¹ In other countries with FP services, the rationale is not so much to reduce fertility but to

¹ It is important to distinguish between population policies and family planning programs. Population policy includes family planning, but also includes a range of measures to influence decisions at the family and community levels as well as education and health programs effecting family size. It also comprises changing laws to encourage small families and providing effective incentives and disincentives (e.g., cost sharing for health and education). A comprehensive population policy must also include policies to cope with the consequences of population growth. This means general development policies that encourage optimal use of resources in agriculture, urban development, and so on.

improve maternal and child health (MCH). The health rationale for family planning, especially for preventing high-risk pregnancies, is proven and especially pertinent in Sub-Saharan Africa where infant and maternal mortality and morbidity rates are high. One of the key elements of primary health care is MCH care, and this includes family planning. By providing the means to postpone childbearing until after adolescence, helping to space births at 2-3 year intervals, and preventing pregnancies after the age of 35, family planning can greatly improve maternal and child health.

7.10 Where the rationale for FP programs is demographic, it is often a matter of controversy whether government has the right to influence the reproductive behavior of the citizens. Clearly, unless population policies command broad popular support, the prospects for reducing population growth rates are dim. And where poor governance is causing people to question the legitimacy of governments, governmental population policies and FP programs tend to be viewed with particular skepticism. It is critical that anti-natalist policies be seen to apply to entire populations and be evenly implemented. Policies can justifiably become discredited when they appear designed to modify the balance of ethnic groups.

7.11 Needed is a deliberate fostering of pluralism in efforts to extend access to FP information and services by encouraging and supporting local government, community and private initiatives. The successful involvement of non-governmental groups in FP in Sub-Saharan Africa strongly suggests the viability of such an approach. Fostering pluralism entails a broad agenda of activities to facilitate local and private initiatives and learn from them. It involves difficult choices about how and where to expend governments' limited technical and administrative resources. Governments must take the lead in promoting the dissemination of FP information and in developing a social consensus on its legitimacy. Especially in rural areas, where the government is the major provider of modern health care and specifically of MCH services, the public sector may have to be the principal provider of FP services for some time to come. Many factors still bear on the ethics of family planning in Sub-Saharan Africa, and these point to the need for a sensitive approach (Sai and Newman, 1989).

(ii) Promoting Demand for Fewer Children

7.12 Even greatly improved supply of FP services will not succeed in bringing about the required declines in fertility, unless demand for fewer children rises considerably.² The evidence of attitudinal and behavioral changes regarding fertility in many parts of the continent suggests that it is possible to create such demand. Between 20 and 40 percent of women in the countries of Sub-Saharan Africa wish to space their children at least two years apart (Table 6). Rising pressure of the rural populations on cultivated land is stimulating demand for smaller family size. Migration and urbanization are loosening extended family ties and raising the private costs of children. Education of women is increasing, there is a clear trend toward later marriage,³ and there are indications of considerable unmet demand for modern contraception (Table 6). These changes in attitudes can be encouraged, promoted and accelerated by a variety of means, including effective information, education and communication (IEC) programs, so as to lead to increased demand for FP services.

² A recent evaluation of past World Bank operations in the population sector confirmed that FP services have been offered in many countries when there was little evidence of any significant demand for them (World Bank, 1991e).

³ Average age at marriage increases with education level -- and this correlation is stronger in SSA than in other regions. This may be because education for women is more rare in SSA and differences in age at marriage therefore reflect the exceptional differences in the lives of the most educated. Since female education is a more recent phenomenon in SSA, the difference in age at marriage may also capture both education and cohort effects. Interestingly, these larger differences in age at marriage were not yet reflected in differences in fertility in the early 1980s (Cochrane and Farid, 1989).

7.13 Improving the legal, economic and social status of women is critical to overcoming the constraints imposed upon them by their traditional roles that perpetuate high fertility. This entails, *inter alia*, recognizing and emphasizing that women's status also derives from their economic contributions to family, community and society. It requires, therefore, expanding the range of opportunities available to them and supporting developments that provide women with greater control over their own lives and the output and income generated by their work. Greater educational opportunities, removal of discriminatory laws, raising the age of marriage, ensuring women's rights to land, improving their access to credit and training, meeting their needs for technology and information, opening up employment and income-earning opportunities beyond those traditionally open to them, and strengthening women's organizations all help to raise women's status and give them greater control over their lives. At the same time, efforts must be made to relieve both the environmental degradation and the work burden on women, both of which fuel demand for additional family labor.

7.14 To promote demand for FP services, actions such as the following are essential:

- (a)** Political leaders and communities need to be sensitized to the environmental and economic consequences of rapid population growth. People's demand for family planning and contraception, as well as for later female marriage, must be increased through widespread IEC programs. In order to ensure that people regard such programs as legitimate, governments must demonstrate continually their legitimacy and credibility, through good governance. Governments lacking credibility and popular acceptance are very likely to confront popular distrust of population programs.
- (b)** Effective measures are needed to expand education, especially for females, and to improve women's income-earning opportunities. This will tend to raise women's marriage age and reduce both their desired and actual number of children. To the extent that improved income-earning opportunities for women lead to increased control by women over such income, this will have strong positive effects on child health and welfare, on infant and child mortality and, hence, on women's fertility preferences.
- (c)** Health services need to be expanded and improved to deal with major epidemic diseases and reduce infant and child mortality. This will increase the security of having descendants at death and weaken one of the major traditional motivations for desiring large families. It will also reduce the economic incentive for having larger families, since fewer, but surviving, children can assure adequate availability of family labor.
- (d)** Expanding access to effective primary health care is also essential to address the problems of sexually transmitted diseases (STDs). STDs are major causes of infertility, which in some regions discourage any interest in fertility control. High incidences of STDs are also an important factor contributing to the rapid spread of AIDS.
- (e)** Incentives for smaller families and disincentives for large families (e.g., limitations on tax deductions for children) may help in the longer term. Community leaders, teachers, agricultural extension agents and the mass media should be utilized to convince people of the economic, environmental and health benefits of having fewer children.
- (f)** Land tenure reform as well as improved access of women to land, to agricultural extension and to credit are likely to reduce the pressure on women to have many children. Greater food security also appears to lead to reductions in fertility rates.

Increasing the Private Costs of Having Children

Some observers argue for deliberate policy actions designed to impose more of the social costs of children directly on their parents. In some countries and under certain conditions, this would create pressure for reducing family size. Where, for example, education is a highly valued commodity, shifting the cost of schooling increasingly to the parents is likely to have a dampening effect on fertility rates. This appears to have been an important factor contributing to the decline in the TFR in Kenya.

Such a policy thrust conflicts, of course, with the important development policy objective to meet basic needs. Moreover, such a policy potentially faces very important pitfalls. There is a very high likelihood that parents would, out of economic necessity, decide to ration access to education among their children, favoring boys at the expense of girls (even more so than is already the case). This would have profound longer-term implications -- not least for fertility rates.

Moreover, in many SSA settings, the cost of children is not necessarily borne by those responsible for their having been born. Not only do fathers often have very limited responsibilities for child maintenance (or evade their responsibilities altogether through divorce or migration), but child fostering is a widespread custom in many societies.

(iii) Improving the Supply of, and Access to, Family Planning Services

7.15 Improving the supply and accessibility of FP services to respond to the demand created by measures such as those outlined above requires the combined efforts of governments, NGOs and aid donors. The target must be to raise the CPR in each country sufficiently to achieve a 50 percent reduction in the TFR by 2030 (Tables 4 and 5). For Sub-Saharan Africa as a whole, this implies increasing the average CPR from less than 11 at present to over 45 by the year 2020 and to over 50 by 2025 (Table 5).

7.16 The family planning effort of nearly every country in Sub-Saharan Africa ranks near the bottom of developing countries, with the notable exceptions of Botswana, Kenya, Mauritius, Zimbabwe and, arguably, Ghana (Table 7). Fertility can be reduced and population growth slowed if governments, schools, employers and NGOs take measures to increase the demand for smaller families while supplying the services needed for families to limit family size. The FP services provided must be of high quality and responsive to clients' needs, and there must be adequate provision for monitoring and evaluation.

7.17 In most countries of Sub-Saharan Africa, FP services are integrated with and delivered through the public health system, usually as part of MCH care. But in many countries the public health system is weak and limited and unable to deliver widespread and effective FP services. Rapid expansion of access to family planning will therefore require strengthening and expanding public health care systems as well as developing alternative and supplementary channels to deliver FP services and IEC. Where AIDS is important, this will be all the more critical, since sex and health education and the provision of condoms are the key instruments for combatting its spread.

7.18 The promotion of modern family planning can build on long-standing traditions of spacing births through prolonged breastfeeding and post-partum sexual abstinence. The significant potential health gains from family planning appeal to policy-makers and to the people affected. And new methods of delivering FP services have been shown to be workable and to make a difference in parts of Sub-Saharan Africa. A focus on birth spacing, rather than on family size limitation, would appear to be most appropriate where demand for fewer children is not strong. This is most common in those countries where the population pressure on cultivated land is comparatively weak and where traditional incentives for wanting large families remain strong.

7.19 Supply and accessibility could be substantially improved by measures such as the following:

- (a) Governments should establish and strengthen public institutions charged with population and FP programs. This will involve staff training, management improvements, and strengthened program content.
- (b) The role of NGOs in family planning should be expanded NGOs have demonstrated their effectiveness in dealing with family planning issues effectively all over the world.
- (c) Private FP organizations, non-governmental health care networks (churches, employers' schemes), private health care practitioners (including traditional health care providers), other non-governmental development groups (women's groups and community associations), non-health outreach networks (agricultural extension and community development workers) can all be effectively used as channels for FP services. So can commercial outlets such as pharmacies, market traders and rural stores, particularly for marketing contraceptives. With AIDS an increasingly severe problem in many countries, a massive effort to expand the range of providers of condoms will be critical.
- (d) Community incentive schemes should be developed and funded to induce communities to take action to reduce population growth through community-managed family planning programs. These programs can be managed, with government funding, by schools, employers and community groups.

7.20 Periodic demographic and health and contraceptive prevalence surveys are needed to establish baseline data and provide essential information on fertility, family planning and maternal and child health to policy makers and planners. Such data would reveal unmet demand for family planning and would indicate where service expansion or improvement is warranted and most needed.

B. Primary Education

7.21 In most countries of Sub-Saharan Africa, two important development objectives are (a) to improve the quality of primary education and (b) to expand primarily school enrollment, especially of girls. Indeed, one of the most critical issues in the education sector in much of Sub-Saharan Africa is the urgency to increase primary school enrollment of girls. In some countries, girls account for less than 20 percent of primary school enrollment and even less in secondary and tertiary education. The lower rates of female school enrollment and the higher rates of female drop-out at earlier grades are due in large measure to the high demand for girls to help with domestic work, such as caring for younger siblings, fetching water and fuelwood, etc. (e.g., Ventura-Dias, 1985, p. 183). Caring for younger siblings is particularly prevalent among girls aged six to nine -- an age at which they should attend primary school. Once they have missed that, their chance to receive schooling is almost inevitably lost forever. These girls are very likely to remain in the low-education, low-income, low-status, high-fertility rut.

7.22 The gender gap in education has a high cost. Primary schooling beyond the first three years lowers women's fertility. Female education also has a strong effect on family welfare: the mother's education may be the single most important determinant of child health and nutrition. Moreover, since the majority of agricultural subsistence producers are women, better education for women can be expected to improve agricultural productivity -- as well as women's incomes, opportunities and decision-making power within the household.

7.23 A number of possibilities exist and have been successfully tried in various settings to increase primary and especially female school enrollment. These need not be repeated here. One such possibility merits mention, as it may be of particular relevance in the present context. It concerns changing school schedules -- daily hours as well as vacations -- to fit better into rural production systems and agricultural seasons. Children will need to help with farm work, especially at peak periods, and if school is scheduled accordingly this may help improve attendance. Current vacation schedules are often still those established prior to independence on the model and patterns of the colonial powers. European school breaks were scheduled to allow child labor in farming activities (planting, weeding, harvesting). The farming seasons in the Sub-Saharan Africa are different. Regional school administrations should be given authority to adjust schedules to local realities.

C. Conclusion

7.24 Rapid population growth is detrimental to achieving economic and social progress and to sustainable management of the natural resource base. But there remains a sizeable gap between the private and social interest in fertility reduction, and this gap needs to be narrowed. Policies and programs which influence health, education, the status of women and the economic value of children in turn influence attitudes toward childbearing, family planning and people's ability to control family size. Efforts to reduce fertility through explicit population policies, therefore, should be integrated with policies to improve health, education and women's status.

7.25 The various components of human resource development programs are strongly synergistic. Family planning is more readily accepted when education levels are high and mortality low and, in particular, when child mortality is low. Healthy children are more likely to attend school. Clean water and sanitation are more beneficial if combined with health education and nutrition education. Educated mothers are more likely to have fewer and healthier children. These human resource development efforts also have positive effects on agricultural productivity and, hence, on food security. This, in turn, stimulates demand for fewer children. Improvements in human resource development are therefore critical in multiple ways for long-term sustainable development.

7.26 Broad-based improvement in human resource development performance requires reorienting policies and financial resources to focus on delivery systems that respond to the critical needs of the vast majority of the population, including the poor. This entails a far greater emphasis on primary education and basic health care. It also requires financial resources and, hence, substantial and sustained economic growth to generate sufficient resources to invest in human resource development (the significant potential and need for improving cost effectiveness notwithstanding). Without substantially improved agricultural growth performance, this will not be attainable.

VIII. PROMOTING SUSTAINABLE AGRICULTURAL DEVELOPMENT

A. Sustainable and Environmentally Benign Agriculture

8.1 As suggested by the analysis in Chapters IV, V and VI, agricultural development efforts must focus on innovations which improve the productivity of land and of farm labor. Incentives which encourage increases in both land productivity and in further expansion of the cultivated area are consistent with agricultural growth objectives, but not with environmental protection concerns. The objective, therefore, must be to increase the productivity of both land and labor, in order to permit output growth while minimizing the increase in the area farmed. The required increase in productivity must be achieved with the least possible destruction of the environment.

8.2 A critical issue to be kept in mind is the extraordinarily high risk faced by most farmers and herders in Sub-Saharan Africa. Rainfall is unpredictable in all but the most humid zones, and much of the continent has a significant chance of drought each year. Even in years of adequate overall rainfall, rains can start late or end early, and dry spells can occur at crucial times in the growing season. Most African soils need skilled management to ensure sustainable production, and most are easily degraded when their vegetative cover is thinned or removed. The dryer areas are dominated by sandy porous soils deficient in nutrients, while many of the humid lowlands have acid soils where aluminum toxicity can damage plants. The most fertile soils are in the East African highlands, where slopes and intense downpours increase the risk of erosion. The dark clay and alluvial soils in valley bottoms are prone to waterlogging and difficult to cultivate without animal traction or mechanized equipment. And the potential for irrigation is limited.

8.3 Crop farming in Sub-Saharan Africa, as in other tropical regions, also is characterized by extreme seasonality of labor requirements and labor peaks (Ruthenberg, 1985, pp. 77-78). Labor shortages are very common at the stages of land preparation, weeding and harvesting. With traditional tools, land can only be prepared once the rains have started -- but then it must be done very quickly to allow sufficient time for crops to grow on the available moisture. With the onset of the rains, growth conditions also become ideal for weeds, and weeding becomes critical. Similar

Peak Labor Periods, Nutrition and Health

All farming systems research in Sub-Saharan Africa shows tight labor constraints at certain critical periods in the crop cycle. One of the most interesting insights from data collected in northern Malawi is the relationship between labor demands and health: most illnesses were reported toward the end of the rainy season (February-April) and most deaths during March-June -- explained largely by reduced food availability, heavy work loads, dampness and water problems in the house (Doe, 1988, p. 334).

urgency prevails at harvest time to prevent crop losses. These labor constraints are compounded by the effects of climate, health and nutrition. In humid tropical and subtropical climates, only light work is possible during the midday and early afternoon hours when there is no shade. Heavy work must be interrupted by frequent and prolonged rest periods. If people are poorly nourished and/or afflicted with disease, their capacity for hard and sustained work is further diminished.¹ An obvious implication of this is the enormous need for labor saving technology in tropical agriculture.

¹ Ruthenberg (1985, p. 78; citing research published by H. Brandt in "Work Capacity Constraints in Tropical Agriculture Development," in *Medizin in Entwicklungsländern*, Heft 8, Verlag P. D. Lang, Frankfurt, Germany, 1980) points out that the "admissible work load" for a healthy person would be 300 kcal per hour in agricultural field work at 27° C (or about 80° F) with no insolation, but only 225 kcal working with full insolation. A sick worker, by contrast, working in full insolation, can only expend about 180 kcal/hour. Work capacity declines very rapidly with rising temperatures. At 30° C, a healthy worker in the shade can put in about 150 kcal/hour, while sick people should be resting in the shade.

8.4 Generally poor and heavily dependent on local natural resources and family labor, farmers and herders in Sub-Saharan Africa cope with uncertainty and with sustainability problems by adopting a variety of flexible strategies that minimize risk and make optimal use of their available resources. Examples of such strategies include planting multiple crops and multiple varieties of multiple crops; diversifying herds and maintaining a high degree of mobility; establishing social arrangements to gain access to additional resources at times of stress; pursuing a variety of off-farm income-generating activities, particularly during the off-season. These strategies seek to diversify income and food sources, stabilize aggregate production and income, minimize risk, and maximize returns to labor under low-technology conditions. In crop production strategies, the central objectives almost invariably are: (a) to ensure optimum stable aggregate output of multiple crops over time, at the expense of maximizing yields of individual crops (see also para. 8.15), and (b) to maximize output per unit of labor rather than per unit of land.

8.5 Farmers seek to maximize production per unit of land only when land becomes scarce relative to labor. This is now occurring in many parts of Sub-Saharan Africa. The weakness of the traditional coping strategies, as discussed in Chapter IV, is that they are not capable of adjusting quickly enough to prevent serious negative impact of rapid population growth and increasing population pressure on soil fertility, farm size, fuelwood availability, land tenure systems, and so forth. The challenge is to increase farmers' and communities' ability quickly and effectively to confront these problems, building on their traditional mechanisms of coping with their environment.

8.6 Another critical issue is that of ensuring the longer-term sustainability of agricultural production systems. Sustainability has several dimensions and must be considered in terms of environmental, technological, economic, social and institutional aspects and constraints and the interactions among them. It also must be considered in a dynamic sense, since there will be change, probably quite rapid in certain areas. If the rapidly rising demand for agricultural products is to be met without further depletion of the natural resource base, this requires modification of agricultural production systems in the direction of intensification (i.e., more output per unit of land).

8.7 There are numerous environmentally benign agricultural technologies which have been developed experimentally on a small scale in Sub-Saharan Africa. Examples include contour farming to reduce water run-off and soil erosion, mulching, minimum tillage, intensive fallowing, crop mixtures and rotations which assure continuous soil cover, terracing and bunding, integration of livestock and cropping to maintain soil fertility, agro-forestry, integrated pest management, and water harvesting. In some countries farmer-managed small-scale irrigation also has considerable potential. Behind each of these terms lies a considerable body of agricultural knowledge which to date has found little application in Africa outside of a number of NGO projects. Accelerating the widespread adoption of such technology, carefully adapted to the widely varying local agro-ecological and socio-economic conditions, is essential if the critical problems faced by African agriculture are to be successfully overcome.

8.8 Such technologies need to be mastered by national agricultural research and extension systems so that they can be more widely adapted to farmers' circumstances. There is a basic constraint, however, which is as much responsible for the lack of successful introduction of these technologies as has been poor research and extension. Farmers have not demanded these technologies – much as most people have not demanded family planning. There has been little incentive for individual farmers to introduce such technologies in place of traditional methods. As Boserup suggested, as long as there is free land to open up for farming, investing labor and capital in more intensive agriculture makes little sense from the farmer's perspective. When inappropriate macro-economic and agricultural policies reduce the profitability of farming, the incentive for farmers to

intensify is further weakened. Policies that encourage opening up of additional farm land are not the answer, however, since these can be environmentally destructive. This complicates the search for solutions to the problem.

8.9 Agricultural intensification on a wide scale therefore requires more effective research and extension. It also requires policies that induce farmers to intensify production. Ensuring that intensive farming is profitable requires the kind of price, tax and exchange rate policy environment suggested in the World Bank's long-term perspective study for Sub-Saharan Africa (World Bank, 1989d). Agricultural input and output prices must be determined not by governmental decree or by monopolistic or monopsonistic parastatal marketing agencies, but by market forces and must be closely linked to world prices. Exchange rate policies must ensure efficient equilibration of international and internal prices. And marketing, trade and investment policies must facilitate private response to market opportunities.

8.10 In the short to medium term, subsidies may be necessary for farm inputs needed to introduce intensive sustainable agricultural techniques, while shifting cultivation and the conversion of further forest and savanna land to crop land may need to be taxed for environmental reasons. Such measures raise the cost of land and improve the profitability of intensification. Another, complementary, approach would involve providing compensation to individuals and communities to offset the gap between private and public costs and benefits of resource-conserving agricultural production methods.² Such subsidy programs would need to be carefully designed and monitored (see also paras. 8.63-8.65).

8.11 The environmentally benign and sustainable technologies of the type noted in para. 8.7 are, by themselves, unlikely to be sufficient to permit most countries of Sub-Saharan Africa to achieve agricultural growth rates of 4 percent per annum. Improved crop variety/fertilizer/farm mechanization technologies will also be necessary, and the most desirable scenario would involve the widespread adoption of location-specific appropriate combinations of both. A gradual shift to locally suitable higher-value crops and livestock products will also be necessary. Over time, this will be stimulated by the policy reforms briefly summarized above. Nevertheless, in certain agro-ecological settings, some trade-offs between agricultural intensification and environmental resource protection will be inevitable. The following sections discuss environmentally benign low-input, low-risk technologies that deserve greater emphasis.

(i) Soil Conservation and Fertility Management

8.12 Soil erosion is influenced by a combination and interplay of many factors – including soil characteristics, climate, topography, land use and farming practices. It is therefore site-specific, and individual control measures that are appropriate and successful in one set of circumstances cannot automatically be transferred without modification to another location.

² If, for example, constructing rock bunds on steep slopes or the afforestation of severely degraded land to prevent gully erosion provide high economic returns, but low financial returns to the farmers and communities who would be undertaking these works, appropriate compensation would be sensible to cover the difference. This might take the form of partly or wholly subsidized provision of key inputs (e.g., seedlings), of direct wage payments (under food-for-work schemes, for example), or of the provision of village-level infrastructure facilities in exchange for community action on resource conservation. This type of approach is discussed and analyzed in detail in FAO/World Bank Cooperative Programme, 1991, and a land resource conservation project in Ghana now being appraised by the World Bank is likely to test this approach in practice.

8.13 Farmers adopt soil conservation measures that they clearly perceive to be in their own interest. In low-resource and labor-constrained settings, and with risk-averse farmers, measures recommended for adoption must increase crop yields (probably by a fairly significant margin), require little or no cash outlay, and conflict as little as possible with existing peak labor demands. If tree planting is involved, local rules concerning tree tenure must be considered, as must the often considerable differences in the allocation of costs and benefits between men and women (see para. 8.41). If men are to invest in tree planting and maintenance, trees must produce cash crops and/or timber (or fuelwood for sale). Women far more readily value trees that provide fuelwood for own use, livestock fodder, fruits and other non-wood products. Many soil conservation efforts require additional labor -- which often has high opportunity costs or is simply not available. Even off-season labor availability cannot be taken for granted. Rural people pursue various non-farm income-earning activities when farm labor needs are slack, and seasonal outmigration of men is common in many areas. The shortage of labor has been one major reason for the lack of adoption of many soil conservation programs. The other has been the perceived low rate of financial return to most of the techniques that would be technically effective. Where, however, the labor/land ratio is high, as in parts of the East African highlands, various labor-intensive soil conservation techniques are financially attractive and, indeed, widely used. It can be concluded, therefore, that farmers' willingness to undertake soil conservation measures will increase as population densities rise, as soil degradation and erosion problems intensify, and as policy reforms make intensive agriculture more profitable.

8.14 African farmers already use a variety of techniques, highly adapted to local conditions, to manage soil fertility and conserve soil. Many of the "more innovative" practices now being evaluated and refined on research stations are in fact based on techniques developed by farmers themselves. These techniques are founded on the recognition that the only truly effective way of controlling soil erosion is the maintenance of vegetative soil cover, especially during the rainy season. Many traditional farming practices contain a number of features that are designed, in part, to meet this requirement: mixed cropping, intercropping, relay cropping, various forms of fallowing, crop rotations, no-tillage and minimum tillage, multi-story farming, a variety of agro-forestry techniques, etc.³

8.15 All these techniques also meet other important requirements. Particularly essential are these: spreading total labor requirements as evenly as possible over the year; making optimal use of cultivated land through spatial arrangement of crops in mixed cropping systems;⁴ and minimizing risk and stabilizing aggregate output from multiple species in environments characterized by considerable climatic uncertainty. It has been repeatedly documented that African farmers "outperform" the weather: indices of crop yields over time fluctuate considerably less than indices of rainfall (Dommen, 1988, p. 27).

8.16 Basing improvements on this rich tradition of farmer ingenuity and adaptation to local circumstances and constraints holds the greatest promise for success in overcoming the problems now facing agriculture in Sub-Saharan Africa. By the same token, failure to recognize this potential and

³ Farmers have also resorted to engineering techniques to combat soil erosion and improve water retention on their farm land. In various parts of the Sahel, terraces, stone lines and stone bunds, and earthen ridges, often laid out in grids, are traditional methods still used in Mali, Burkina Faso and Niger. Most of these techniques continue to be used, but terrace maintenance is increasingly being neglected due to labor constraints (Reij, 1988, pp. 19-23).

⁴ In mixed cropping systems in the humid tropical forest zone, 20 to 30 different species appear to be the "norm" on a single farm, but as many as 60 species have been found. In the semi-arid regions, 15 to 20 species appear to be the normal range for a single farm (Dommen, 1988, p. 36).

to tailor supportive efforts accordingly has been an important factor contributing to the non-adoption of many technical "solutions" proffered in the past to overcome Africa's agricultural crisis.⁵

8.17 Numerous effective and low-cost or no-cost techniques can be made available to African farmers that would permit intensification and greater sedentarization, improve yields, and maintain soil fertility. Which of these are appropriate — technically and economically — depends very much on local conditions. A few examples of techniques aimed at soil conservation and soil fertility management are the following:

- Vegetative soil and water conservation methods are highly effective and far less labor-intensive to establish and maintain than terraces and other soil-moving techniques. Except on very steep slopes, grassy strips (sometimes called infiltration bands) have been found to be as effective in combating erosion as bench terraces — these being the two most effective techniques. Permanent strips of suitable species, established on the contour at proper intervals down the slope, are highly effective in slowing runoff, reducing soil erosion, improving moisture retention, and creating natural terraces over time. If fodder grasses are used, periodic cuttings provide animal fodder. Variations of this method are already in use, for instance, in Ethiopia, Kenya, Madagascar, Nigeria, Rwanda and Tanzania.⁶
- Where draft power is available, ploughing along the contour on sloping land will considerably reduce soil erosion and increase water infiltration. The effectiveness of contour farming is further improved if permanent contour key lines are established at appropriate intervals down the slope by means of permanent strips of suitable plant species (such as *Vetiveria spp.*).
- Mulching can considerably reduce soil erosion, improve in-situ water retention, raise soil fertility and increase yields. But mulching annual crops is difficult. It can only be done after the seedlings have emerged, so that the mulch will not prevent germination. Consequently, mulch will not be in place at the onset of the rains, when much soil erosion takes place. Moreover, many annuals are low to the ground and mulch, with its micro-environment that harbors insects and molds, is close to the leaves of the young plants. The techniques of annual crop mulching are proving to be extremely demanding. Most experimental work in this area has been conducted by the International Institute of Tropical Agriculture (IITA), which has generally had to resort to pesticides (Jones and Egli, 1984).

⁵ A long-time student of the situation in northern Nigeria has written that the "basic rationality" of indigenous land-use systems "emerges unfailingly from almost every field investigation" and "the rationale of indigenous land-use systems must become the basis for conservatory resource management for the simple reason that the land belongs to, and must continue to be occupied by, its present population" (Mortimore, 1989a, p. 207).

⁶ For best effect, the species used should be either a grass or a shrub with deep roots and strong and dense leaves and stems; it should be drought, fire, livestock and flood resistant, should not take up much crop land, and should not harbor pests or diseases. *Vetiveria zizanioides*, a clump grass, exhibits all these characteristics and more. It thrives in arid and humid conditions, seems to grow on any soil (including shallow rocky soils) and survives wide temperature ranges. It is virtually maintenance-free, produces a dense hedge, and is extremely effective in trapping silt, slowing runoff and increasing water infiltration. It is used for soil conservation purposes in regions as diverse as China, Fiji and India. Extension services in Nigeria, following successful field trials, are now promoting its use, as well as that of its close relative *Vetiveria nigrivana*, as a vegetative erosion barrier; *V. nigrivana* has long been used by farmers in parts of northern Nigeria to mark their field boundaries.

- **Minimum tillage and no-tillage methods, which involve planting directly into a stubble mulch without ploughing or hoeing, can virtually eliminate soil losses, increase water infiltration and retention, and reduce labor input per unit of output. Minimum tillage is, of course, a practice very familiar to farmers in forest fallow systems. Soils in forest fallow systems are, however, almost entirely free of weed seeds and extremely easy to work with a planting stick. Neither condition is likely to apply in minimum tillage or no-tillage systems practiced on more permanently cultivated land.**

Alternatives to Slash-and-Burn

Results of ICRAF field tests of environmentally benign, low-input sustainable technologies for tropical forest areas suggest that farming on newly cleared land must begin with low-input cropping. The initial slashing and burning clears the land, adds nutrients to the soil, and reduces soil acidity for the first year of cultivation (tropical forest soils generally being very acidic). Acid-tolerant crops such as upland rice and cowpeas should then be planted. First-year yields are usually very high. All crop residues (cowpea tops and rice straw) should be returned to the soil to improve its organic content. The plot should then be sown to pasture legumes or grasses; kudzu is recommended because it grows easily and smothers weeds. This "managed fallow" is more effective than the traditional forest fallow in restoring soil fertility. In subsequent years, more intensive techniques are necessary to maintain soil fertility. This may involve agro-forestry, tree crops, legume-based pasture or, if the farmer can afford it, farming based on adding chemical fertilizers (Sanchez, 1991).

- **"Intensive" or "managed fallowing" -- sowing deep-rooted legumes when land is taken out of production, rather than simply allowing natural revegetation to take place -- can greatly improve soil fertility even in a single year. Where new land remains available for clearing, however, or where livestock are allowed to graze fallow land, farmers may be slow to change their fallowing practices.**

8.18 Labor-intensive approaches and mechanical or engineering works (such as terracing and bunding) are suitable only in certain settings. Moreover, engineering works will not be satisfactory in isolation. The primary requirement is appropriate land use, and mechanical conservation works must be accompanied by good farming practices (Hudson, 1987, p. 158).

- **Terracing is common in some parts of Sub-Saharan Africa, mainly on steeply sloping land.⁷ When properly constructed and maintained, terraces are highly effective in preventing soil erosion and increasing the retention of water in the soil, but they have drawbacks. Most important, they require considerable labor to construct and maintain and are far more expensive per ton of soil retained than any other alternative for soil erosion control.**
- **Earthen bunds also require frequent maintenance and repair. Unless properly maintained and stabilized with grasses, they last only two to five years.⁸ On slopes of more than 10**

⁷ From 1976 to 1985, with support from several external aid agencies, Ethiopian farmers constructed 60,000 km of bunds and 470,000 km of terraces for reforestation; however, this amounts to just 6 percent of Ethiopia's threatened highlands.

⁸ In Burkina Faso, earth bunds constructed in the early 1960s to protect some 120,000 ha in the Yatenga region have not been maintained and virtually disappeared. Earth bunds built between 1973 and 1985 by the Fonds de Développement Rural to protect about 48,000 ha on the Central Plateau in Burkina Faso have also not been maintained by farmers. In Niger, the experience has been similarly disappointing. Earthen bunds built in the 1960s to treat 2,000 ha in the Maggia Valley and in the 1970s to protect 4,000 ha in the Badéguichéri Valley were not maintained and are today largely degraded (Reij, 1988).

percent gradient, they silt up rapidly; their trap efficiency may be 30 to 50 percent in the first year but falls to zero in the second (Grimshaw, 1989). They have been found useful only on well-drained soils. Elsewhere, they are susceptible to breaching and failure and cause water logging.

- In Rwanda and Burundi, contour ditches introduced by colonial governments to control soil loss were abandoned after independence because farmers, who have a good idea of the cost in labor of digging and maintaining ditches, felt the ditches were not worth the maintenance they required (Brown and Wolf, 1985, p. 42; Jones and Egli, 1984). The practice is now slowly being reintroduced, along with tree planting, mulching and other complementary conservation measures.
- On the Yatenga Plateau in Burkina Faso, farmers have adopted a technique of ranging lines of stones along the contour on land suffering from, or threatened by, erosion. The lines of stone slow water run-off, increase water infiltration, trap dislodged topsoil and have helped revegetate heavily degraded land. Farming had become threatened, and because labor was available to carry out the work, this comparatively heavy investment in soil conservation and land improvement works made economic sense to farmers. Some 6,000 ha have now been "treated" in this manner, and yields have increased by 15 to 30 percent. Labor cost are high and increasing, however, as rocks now have to be brought from increasingly greater distances. The success of the stone contour bunds in the Yatenga Region could not be replicated in Mauritania's Affole mountains, where rainfall is much lower, slopes are steeper, and the population density far lower. This underscores the limitations to "technology transfer" and the critical importance of adapting "solutions" very carefully to local agro-ecological and socio-economic conditions (Reij, 1988, p. 27).⁹

8.19 Kenya offers an example of a promising combination of conservation and new farming practices that increases vegetative cover and reduces the likelihood of severe erosion. Farmers are free to choose which practices to adopt and which trees to plant. Hundreds of thousands of smallholdings have been terraced by now, with farmers doing the work themselves (see box on p. 89).

8.20 There are a number of other simple but effective ways in which farmers' production systems can be made significantly more productive and sustainable, without increasing farmers' risks or the requirements for additional labor and/or capital beyond what the productivity gains will cover. Table 24 summarizes the results of a financial and economic analysis of many of these techniques under currently prevailing conditions in Nigeria (FAO/World Bank Cooperative Programme, 1991). This analysis showed that many of these techniques are highly effective in reducing the decline of crop yields on continuously cropped land by reducing, to varying degrees, soil fertility losses and erosion. Almost all of the techniques assessed showed high economic rates of return and financial rates of return of 10 percent and more. However, the pitfalls of attempting to introduce such techniques on a wide scale are also evident in these data. A few, such as stone-faced terracing and

⁹ Another interesting dimension of the stone line technology was observed on the Mossi Plateau in Burkina Faso. There, women do not own land and do not benefit directly from the profits of their husbands' fields. They do, however, benefit directly from working on their collective fields, which are "borrowed" from the men, because the yields are distributed to all participants. Most women were soon discouraged from building rock lines. They had labored hard to treat their fields, but then often found the men reclaiming these improved plots for their own crop production and forcing the women to move again to another untreated piece of land (Wardmann and Sales, 1991, p.77).

Soil Conservation in Kenya

In Kenya, grass-roots interest in soil conservation began to emerge a few years after independence, encouraged by good leadership and a strong sense of national unity based on the *harambee* philosophy. An important step was the adoption of soil conservation by the *Mwethya* groups, voluntary self-help groups which form *uoas* to carry out communal work during the dry season and disband with the onset of the rains to tend to their individual farming activities. Leadership comes from the women, but men are persuaded to join for some physically demanding tasks. The range of activities includes bush clearing, water carrying, management of grass and tree nurseries, and ploughing arable land on group members' farms in turn.

Presidential support for a national conservation program and the creation of a Permanent Presidential Commission on Soil Conservation and Afforestation provided a strong boost to this movement. At the same time the increasingly serious problem of soil erosion in Kenya attracted the attention of national and international aid agencies, who supported development projects which include soil conservation elements. In 1974, the Ministry of Agriculture began a soil conservation extension program with the assistance of SIDA. Farmers were encouraged to terrace sloping land by leaving unplowed strips along the contour, and the concept of a new type of terrace called *Fanya juu* (meaning "throwing upwards") emerged: a ditch is dug on the contour, with the excavated soil placed on the uphill side to form a bund. The steeply sloping riser and the bund are planted with grass, providing a self-terracing effect as the grass and the bund retain soil washed down the cultivated inter-terrace strip.

To compensate farmers for keeping some land out of crop production, fruit and fuelwood seedlings and cuttings of quality fodder grasses were provided for the unplowed strips. Tree crops diversified the produce farmers could sell. High-quality fodder enabled farmers to limit the free grazing of cattle. Terraces retained water and soil and raised yields on the upslope side. In semi-arid Machakos district, maize production in some fields increased by half after introduction of the terraces.

By 1983, terraces had been built on 100,000 farms, and extension agents were reaching over 30,000 new farms each year (Brown and Wolf, 1985, pp. 41-42; Hudson, 1987, pp. 165-166).

improvements of grazing reserves, are either unprofitable or only marginally profitable. Moreover, even a financial rate of return of 10 or 15 percent may not be sufficient to induce investment by farmers whose private discount rates are likely to be as high as 25 percent and more because of the high uncertainties and distorted markets they face. However, as the costs of soil degradation and erosion rise, as labor availability increases, as economic policy renders agriculture more profitable, the financial returns to these measures will increase. Knowledge transfers through extension workers will find an increasingly favorable reception by farmers as these changes occur. This is evident in the Kenya and Burkina Faso cases reported above, in farmer investment in stone terracing and tree planting in Ethiopia, and in windbreak establishment to protect millet fields in Niger (FAO/ECA, 1992, pp. 10-11).

(ii) Water Management

8.21 Highly variable rainfall in many parts of Sub-Saharan Africa makes water conservation vital, particularly in semi-arid areas and where dry spells are frequent. In the Sahelo-Sudanian zone in particular, moisture deficiencies pose the primary constraint on cropping, and effective water management is critical to reduce erosive and wasteful runoff and to maximize water infiltration into the soil. In most settings, in-situ water management through improved infiltration and moisture conservation is likely to be far less costly, more effective and less stressful for the environment than the construction of water harvesting and storage structures. Many techniques recommended to combat soil erosion (e.g., contour farming, establishing vegetative contour strips, intercropping, ridging) are, of course, extremely useful for in-situ moisture conservation.

8.22 However, under certain conditions (notably in low-rainfall areas), water harvesting techniques may be both necessary and effective. Water harvesting involves the collection and

utilization of runoff for farming (or other uses). A very common form of water harvesting involves collecting runoff from a large area by means of earthen or stone bunds and guide it through ditches or channels on to smaller areas where field crops or trees are grown. Another common traditional technique is waterspreading: diverting runoff from seasonal streams or gullies to cultivated fields. By increasing the quantity of water available on cultivated land, these and other water harvesting techniques greatly improve land productivity; they usually require little capital and are labor-using. Water harvesting has proven effective and successful, for example, in Burkina Faso's Yatenga Region and in Kenya's Baringo District.¹⁰

8.23 In many countries (e.g., Chad, Ethiopia, Malawi, Mali, Nigeria, Senegal, Uganda), the productivity of farm land can also be improved in a manner consistent with resource conservation objectives through irrigation development. Only about 5 million ha are irrigated in Sub-Saharan Africa today,¹¹ about half by modern means and the rest by traditional small-scale methods. The additional area potentially suitable for irrigation is estimated at about 15 million ha (Barghouti and Le Moigne, 1990, pp. 9 & 13) – not much in terms of Sub-Saharan Africa's total potential farm area. Moreover, irrigation development in many parts of the continent would entail very high environmental costs in terms of increased threats from water-related human diseases and of irreversible damage to ecologically valuable floodplain ecosystems (*ibid.*, p. 13). Nevertheless, in a number of countries, notably those of the Sahel, irrigation development holds considerable promise.

8.24 The emphasis should lie on individually or communally managed systems with development costs of US\$2,000 per ha or less, which can be developed and maintained by individual farmers themselves or by farmers' groups. Such low-cost schemes include irrigation from wells or pumps, controlled flooding, and small-scale development of inland valleys and flood plains. Such developments have often spread spontaneously. Good examples are the private small-scale schemes developed by Mauritanian farmers in the Senegal valley, the rapidly spreading development of small groundwater irrigation systems in northern Nigeria's *fadama* areas (alluvial river valley bottoms), and shallow aquifer exploitation with low-cost tubewells and pumps in Chad and Niger (Brown and Nooter, 1992).¹²

(iii) *Livestock Production and Utilization*

8.25 Mixed farming systems, combining crop and livestock activities, show promise in meeting environmental sustainability criteria. Farm animals are an important link for recycling resources within the farming system and, in the case of draft animals, represent a major step towards farming system intensification and, through the provision of transport services, market orientation. Indeed, the still largely unutilized potential for using animal traction in both farm operations and transport needs to be realized. Cattle acquisition and maintenance involve considerable capital expenditure, however, and are therefore likely to be feasible only for relatively better-endowed households. In

¹⁰ See Reij, Mulder and Begemann (1988) for an extensive review of technical, environmental, agronomic, economic and sociological aspects of water harvesting.

¹¹ Only three countries -- Sudan (1.75 million ha), Madagascar (0.96 million ha) and Nigeria (0.85 million ha) -- account for more than 70 percent of this total (Barghouti and Le Moigne, 1990, p. 7).

¹² Brown and Nooter (1992) review a number of successful small-scale irrigation schemes in the Sahel and identify several common characteristics: simple and low-cost technology; private and individual institutional arrangements; adequate infrastructure to facilitate access to inputs and output markets; active farmer participation in project design and implementation; and high financial (cash) returns to the farmer (pp. x-xi).

any case, switching to animal draft power becomes economical only when the cost of hoe cultivation exceeds the cost of the transition to animal power. This usually happens only with the emergence of continuous cultivation.¹³ Moreover, animal traction is generally adopted first to provide transport services, and only later for purposes of land preparation (Pingali *et al.*, 1987). Maintaining draft animals will not be economically attractive to farmers if their sole use is in land preparation. This suggests that developing rural transport infrastructure -- roads, tracks and trails suitable for animal-powered traffic -- is important to accelerate the incorporation of draft animals on a wide scale into rural economies and farming systems. In addition, upgrading rural transport activities -- notably the movement of farm inputs, farm output, fuelwood, construction materials and water -- from headloading to animal-powered means, will greatly reduce the pressure on women's time.

8.26 Nevertheless, there is good potential for greater incorporation of livestock components into existing farming systems. In many of the mountainous areas, this process is already well underway. Approaches and solutions will vary. The full potential of sheep, goats, pigs and poultry has not been exploited in much of the region. Small ruminants, especially if herded together, are very efficient users of a wide variety of forage and browse resources. They are less restricted by seasonal variations in feed resources and maintain their body weight far better throughout the year than cattle. They also withstand the effects of drought, even a prolonged one, and recover far more quickly from its impact than do cattle (FAO, 1991, pp. 28-36). Goats, pigs and poultry are likely to be more easily integrated into farm operations managed by women, because they tend to stay near the compound. Sheep present a different management issue because they require herding (and this may have implications for boys' school attendance).

8.27 In humid and sub-humid zones, the tsetse fly can be controlled through low-cost traps and spraying, but not eliminated. Priorities for promoting the integration of cattle into farming systems should be to popularize cattle breeds such as the N'Dama which are tolerant to trypanosomiasis and at the same time to develop transport and farm equipment which such animals can power. Also important in the sub-humid zone, where cattle are concentrated, will be the development of fodder banks to provide feed reserves for the dry season; analysis in Nigeria has shown this to be potentially quite profitable (Table 24).

8.28 In the drier cultivated zones, the integration of cattle into sedentary crop farmers' production systems will generate increasing pressure on the available pasture and forage resources, leading to stiffer competition and potential conflicts with transhumant pastoralists whose herds graze on crop stubble and bushy fallows during the dry season. The pastoralists' difficulties are further exacerbated by the increasing development of river valley bottoms in many parts of the Sahel and Sudan for cropping, often year-round by means of small-scale irrigation facilities, because this closes off essential migration routes and feed resources for their herds during the dry season. Improved land allocation between pastoralists and farmers to permit both to survive would be desirable, but no effective means of achieving this has been found as yet. Better land use planning and appropriate land tenure arrangements would be needed.

8.29 Traditional pastoralists are very efficient users of the meager rangeland resources in the arid and semi-arid zones. They possess an enormous knowledge and understanding of the desert and savanna ecologies in which they live and upon which their economies depend. Their husbandry of land, water, vegetative and animal resources and their migratory movements are highly skilled,

¹³ The switch from hoe to plow tillage is usually motivated by the desire to expand the area cultivated or to economize on the labor required for land preparation (Pingali *et al.*, 1987, p. 104).

complex and organized, reflecting generations of careful observation, experimentation and adaptation. Their livestock production systems are, as recent studies have demonstrated, extremely productive. They utilize the marginal resources to which they have access not only very efficiently, but also in a manner that is environmentally sustainable over time. Traditional pastoralists produce as much protein per hectare as do ranches in areas with similar rainfall in Australia and the United States – but with vastly lower capital inputs (Bass, 1990; Odhiambo, 1991, pp. 79-80; Independent Commission on International Humanitarian Issues, 1985).

8.30 But the potential for increasing the output and productivity of pastoralist production systems is low. Moreover, the most critical aspect of their traditional resource management system -- mobility -- is under increasingly severe pressure as sedentary farmers appropriate land resources for cropping, close off vital migration routes and seasonal feed sources, and lay claim to scarce water resources. Forcible (and often violent) prevention of herd movement across state borders as well as armed raids on herds to procure food supplies for rival factions in civil wars further threaten pastoralists' production systems and way of life. Overgrazing is acute around public waterholes and urban centers and a major cause of environmental degradation. In these regions, water resource development and utilization require a refocusing of efforts to develop a network of more widely dispersed wells tapping shallow aquifers. At the same time, water and range resources should be placed under local communities' control and management to help prevent excessive concentration of livestock.¹⁴ Integrated water/livestock/forestry management is required instead of investment and policy efforts which stress one objective to the detriment of overall efficiency and/or environmental sustainability.

8.31 To improve the incentives for livestock production, the linkages from rural producers to urban consumers of meat and milk need to be strengthened. Several countries in Sub-Saharan Africa, including Kenya and Tanzania, are now developing cooperative dairy collection and marketing systems, similar in some respects to the highly successful Indian model. Other countries, such as Ghana and Nigeria, are considering to do the same. Restrictions on cross-border trade in live cattle should be eliminated to improve producer incentives and simultaneously consumer access to meat. Private abattoirs should be licensed (and regularly inspected) to provide market outlets for livestock producers and to serve large urban concentrations of demand for meat. The provision of veterinary services should be increasingly left to the private sector. National animal health services should concentrate on regulating private veterinarians, organizing and subsidizing mass vaccinations, and undertaking other emergency measures. In the more remote pastoral areas, improved livestock care should be provided through "para-vets" compensated through commissions on veterinary drug sales. In all areas, agricultural extension workers should be made fully competent in improved animal husbandry, forage production and animal traction.

(iv) Inputs

8.32 For environmental as well as cost reasons, emphasis should be placed on the use of organic fertilizers. The integration of livestock into farmers' production systems is especially important in this regard. Similarly, disease and pest control efforts should emphasize cultural and biological controls.¹⁵ To support this, subsidies on inorganic fertilizers and pesticides should be

¹⁴ This argument is well developed in Shanmugaratnam *et al.* (1991).

¹⁵ Greathead and Waage (1983) discuss a variety of possibilities for biological control of agricultural pests, and a substantial body of further research findings has been accumulated since then. See also Singh (1990).

removed. Needed are pest- and disease-resistant varieties, as well as cultivation methods and intercropping and crop rotation systems that reduce the spread of pests and diseases. Some positive results in this field have been achieved, for example, by IITA. Integrated pest management (IPM) programs for rice and other tropical crops have been developed that minimize the need for chemical pesticides, yet many governments continue to provide substantial subsidies on chemical pesticides that reduce farmers' incentives to adopt such techniques. Past efforts at biocontrol of pests have focused on predators and parasitoids of insects, but research is now also being directed at the development of biopesticides to replace chemical pesticides and of plant pathogens to replace herbicides. Research in all these areas deserves strong donor support.

Indigenous Pest Control Practices in The Gambia:

Harvested cowpea seeds are steamed or stored in oil, ash or chilies to repel cowpea weevils. Broadcasting wood ash on plants, especially vegetables, is widely practiced. Fresh cow dung, bran or green baobab fruit are used to attract insects to a site away from the field, where they are killed by burning or burying. Burying of blister beetles is reported to produce an odor that repels other blister beetles. Dried neem tree berries are pounded and used as seed dressing to ward off field pests (Norman *et al.*, 1988, p. 311).

8.33 Chemical fertilizers and pesticides will be important, even essential, components of intensified cropping systems. But they are costly in terms of foreign exchange, and their subsidization discourages the use of available and less expensive alternatives. Policy and infrastructure constraints to the use of chemical farm inputs need to be removed, however. There are no gains to be obtained from shifting to an anti-chemicals bias in agricultural policy.

The International Institute of Biological Control (IIBC), an affiliate of CAB International conducting R&D in integrated pest management (IPM), is exploring the use of pathogens and the development of biopesticides to replace chemical pesticides and of plant pathogens rather than herbicides to eliminate weeds. Fungi sprays are being tested, in collaboration with IITA, under Sahelian conditions to ascertain their utility in combating locusts. In collaboration with the Département de Formation en Protection des Végétaux of Niger, a fungal pathogen effective against desert locusts has been isolated and is being tested, along with strains from Pakistan, for incorporation into formulations for field trials. Based on the confirmed key role of predatory ants and bugs against the *Helicoverpa armigera* moth, local IPM techniques are being developed to combat moths which attack cotton, sunflower and other African crops (CAB International, 1991).

8.34 Improved agricultural tools and equipment are essential. Many small "appropriate technology" projects supported by voluntary agencies have successfully introduced simple yet effective devices that require little maintenance and are cheap and easy to use. Equipment for milling, shelling, dehulling, initial conditioning and processing of crops and conservation of seeds offers many benefits in terms of raising productivity and allowing farm women to spend more time on other tasks. Small carts, wheelbarrows and bicycles could substantially reduce the drudgery and time required to transport agricultural produce and inputs both on the farm and to markets. These innovations have been largely neglected outside programs and projects supported by NGOs. They deserve far more emphasis in research and extension programs as well as in endeavors to promote local artisanal and small-scale industry.¹⁶

The International Centre of Insect Physiology and Ecology (ICIPE) in Kenya is working on various techniques that would eliminate the threat of periodic devastating desert locust invasions into Sahelian farming regions. Work is ongoing to utilize the locust's natural enemies (parasitoids and pathogens), but more importantly to utilize pheromones to control the locusts' gregarization and sexual maturation and thereby prevent the emergence of marauding locust swarms while facilitating the locust's continuing existence as an important part of the savanna ecosystems (Ochiambo, 1991, p. 81).

¹⁶ A Bank-supported transport project in Ghana is moving in this direction: it supports the local manufacture of bicycles, bicycle trailers and wheelbarrows and, working with local NGOs, their acquisition by local women under a hire-purchase system linked with a labor-intensive road construction and maintenance and tree planting program (World Bank, 1990c).

(v) *Agro-Forestry*

8.35 From an environmental and agricultural perspective, agro-forestry holds high promise. There are a variety of techniques and approaches for different agro-ecological conditions and production systems which can increase farm productivity and incomes and simultaneously improve the prospects for environmental sustainability of rural production systems (Nair, 1990). Indeed, a multitude of agro-forestry systems and practices are already in use in different parts of Sub-Saharan Africa (Cook and Grut, 1989). Utilizing indigenous trees and shrubs, these are appropriate, low-cost, low-risk and high-return means for maintaining soil fertility, improving soil structure, recycling water and nutrients from lower soil strata, combating soil erosion, and providing secure supplies of fuel, fruits, fodder, mulches, building and fencing materials, and the like.¹⁷ Increased supply of tree products from agro-forestry will help preserve the remaining forest resources.

8.36 Whether agro-forestry efforts should be based on individual or some form of communal planting will need to be determined at each site and with each community. Farm forestry is likely to be more readily incorporated by farmers into their production system in densely populated areas where common forests are no longer available and wood needs must be met from the farm or where wood fetches a good market price. This is already happening in parts of East Africa: there may now be more trees in Rwanda than at independence, even though the natural forests have all but disappeared.

8.37 If trees are to play a greater role in soil conservation and agricultural production, it must be in the farmed area, through agro-forestry on farmers' fields. This can take many forms: shade trees in and around living areas; live (wood-producing) fences replacing dead (wood-consuming) fences around fields and homesteads; and trees and shrubs planted very closely in lines along the contours of sloped fields to prevent soil erosion. Cocoa, coffee, rubber and tea are valuable not only as cash crops, but also as environmentally important components in agro-forestry systems. More species should be added, especially trees that produce fruit, nuts or fodder. Trees can also diversify the basis of food production. In semi-arid areas where wind is a threat to farming through desiccation and/or eolian erosion, windbreaks can be very beneficial. Appropriately designed and managed multipurpose windbreaks of mixed species and heights are particularly attractive, since they will also yield sustainable flows of fuelwood and/or other tree products for the local people.¹⁸ In humid areas, multi-story farming may be desirable, in which various trees, shrubs and crops of various heights are intercropped to provide total and continuous ground cover and a variety of micro-climates. In humid and sub-humid areas, alley-cropping – a variation of traditional agro-forestry practices adapted to sedentary farming – may be effective and adopted by farmers, if the labor requirements involved can be made to fit actual on-farm labor availability. Crops are grown in 4-8 m alleys between rows of leguminous trees such as *Leucaena* or *Gliricidia*, with the prunings providing fuelwood, stakes and fodder, or nitrogen-rich mulch for fertilizer. Agro-forestry systems also hold

¹⁷ The presence of *Acacia albida*, a leguminous tree commonly found in fields sown to millet, sorghum or groundnut in much of the Sahelo-Sudanian Zone, consistently increases the yield of the associated field crops. The tree has many appealing features. One is that it drops its foliage during the rainy season.

¹⁸ CARE began the Majjia Valley Windbreak Project in Niger in 1975. Farmers have now established some 350 kilometers of windbreaks to protect about 3,000 ha of rainfed millet and sorghum fields. Crop yields in protected fields have been 15 to 23 percent higher than in neighboring unprotected fields. – Once fully established, the annual sustainable yield of firewood from the *Azadirachta indica* used in these windbreaks is about 5 kg per tree. Spaced 4 meters apart, 400 m of double-row windbreaks provide 1 ton of fuelwood annually (Nair, 1990, p. 45). The seed pods of *Acacia scorpioides*, also used in windbreaks in Niger, are sold for use in leather tanning (*ibid.*, p. 45).

considerable promise in the context of buffer zone development around environmentally valuable forest stands that should remain under protection (para. 10.15).

8.38 Agro-forestry investments will not be undertaken unless there are adequate incentives at the farm level to produce trees for own use or for the market. The emergence of such incentives depends on a combination of factors. Climate, stage of deforestation, institutional arrangements, tenurial conditions, effectiveness of forestry extension and other factors all are important (Barnes, 1990a; 1990b) – along with pricing. If trees are to be grown for sale as fuelwood or construction material, it must be profitable. Such incentives are gradually emerging. As populations grow and trees are felled, fuelwood becomes scarcer, and this scarcity creates a market value for fuelwood. However, the market for fuelwood is developing too slowly for the reasons discussed earlier. The development of fuelwood markets will be accelerated if: cutting in protected forest areas is restricted; farmers are not restricted or licensed/taxed in marketing fuelwood they produce on their farms; nurseries are established to produce appropriate species; research and extension services incorporate tree farming as a major theme; and land tenure reform provides ownership of forests to farmers and local communities, so that they are more likely to invest in forests rather than simply mine them for fuelwood. If appropriate price signals are to be developed, fuelwood must not be obtainable as a free good. Provided the appropriate species are used, agro-forestry techniques can, however, be very profitable in many areas because of their potential to generate a combination of benefits (fuelwood, poles, fodder, fruits, and associated crop yield increases).

8.39 Economic pricing of woodfuels is critical to encourage conservation and interfuel substitution. Pricing policies based on taxing incoming supplies would encourage economies in the use of woodfuels in urban areas (UNDP/World Bank ESMAP, 1988). Such policies can also provide a way to raise revenues that could be used to improve the forestry services (Falloux and Mukendi, 1988). Higher taxes could be levied on fuelwood coming from open access areas and lower taxes on fuelwood coming from wood plantations and private plots.

8.40 In many regions, there are significant socio-cultural obstacles to widespread tree farming, at least in the short run. In Kenya's Kakamega District, for example, women are not allowed to plant trees because this would undermine their husbands' authority; they are subjected to superstitious threats of barrenness or the death of their husbands (Aloo, 1985, p. 28). In many communities, trees have rarely been deliberately planted – even where their utility is recognized and they are protected and prized for their contribution to livelihood systems. Trees may in fact be regarded as an obstacle to crop cultivation, especially where tenurial considerations (e.g., separation of usufructual rights to land and to trees) or technology aspects (e.g., animal or mechanized ploughing) are important. In some countries, because all forest land is owned by the state, people fear that if they plant trees their land will revert to the government. In parts of the Sahel, farmers are unwilling to plant certain trees because they are on the forest department's protected list, and to crop or prune them would require going through tedious procedures to prove they own the land and planted the trees and to obtain a cutting permit (Timberlake, 1986, p. 56).

8.41 It is important to involve the local women in any projects that concern fuelwood production, provision and use. Men and women almost always have vastly different views concerning the utility of community or farm forestry activities (Molnar and Schreiber, 1989). In Senegal, the men in the village councils planned to sell as poles the timber from community woodlots, which had in fact been established to provide fuelwood for local households and to reduce local women's work load (Dankelman and Davidson, 1988, p. 54). Where women are actively involved, chances of success are high. In The Gambia, for example, the National Women's Bureau and the Forestry Department promoted the establishment of woodlots-cum-orchards managed by village

women's groups, and these are now producing locally significant quantities of fruits and vegetables as well as fuelwood (Marenha, 1985, p. 56; Dankelman and Davidson, 1988, p. 21). Where women face traditional restrictions concerning the planting of trees, careful investigation may reveal possibilities, acceptable under local norms, to plant certain species of brush that are suitable for fodder and/or fuel.

8.42 Several very successful programs in Kenya are based on strong involvement of local women. One of the best known and most successful non-governmental afforestation programs is the Green Belt Movement, started in 1977 by the National Council of Women of Kenya (Maathai, 1988). Another successful program is that of the Kenya Energy Non-Governmental Organization (KENGO), an association of over 200 NGOs dealing with energy issues, which includes a number of women's groups and organizations. KENGO is active in the promotion of fuel-saving stoves as well as in reforestation with indigenous trees. Information on medical, cultural, ecological and economic values of trees is collected from local women and passed on to women's groups through workshops, exhibitions, mass media, publications, etc. The Kenya Woodfuel Development Programme promotes a self-sustaining system of tree planting to supply fuelwood. Based on surveys of agroforestry practices and cultural background of local people, its approach accommodates indigenous expertise with traditional beliefs and taboos. Women are especially encouraged to formulate solutions that will not conflict with traditional values (Chavangi, Engelhard and Jones, 1985; Leach and Mearns, 1988, pp. 142-145).

(vi) Stoves that Save Fuel and Women's Time

8.43 A second major thrust of ongoing efforts to address the fuelwood and household energy problems aims at improving the efficiency of energy use: slowing the rise in fuelwood consumption by introducing more fuel-efficient wood and charcoal stoves. Most rural women in Sub-Saharan Africa cook on some version of the three-stone stove or on other primitive stoves whose energy efficiency is 10 percent or less. Various technical improvements have been advanced, tested, promoted – and usually not adopted by the women for whom they were intended. On the whole, little headway had been made by the mid-1980s with attempts to popularize fuel-efficient stoves or stoves using non-wood energy sources (e.g., solar cookers): few programs had distributed more than 5,000 to 8,000 stoves (WRI/IIED, 1987).

Under the Women and Energy Project initiated in 1984 by Maendeleo Ya Wanawake in Kenya, supported by GIZ, local women are trained to construct low-cost one- and two-pot woodburning stoves with clay liners, which use considerably less wood and allow the kitchen area to be kept much cleaner. This is backed up with training in agro-forestry techniques and establishment of nurseries and fuelwood plantations by village women's groups (Dankelman and Davidson, 1988, pp. 85-86).

The USAID-funded Kenya Renewable Energy Development Project, launched in 1982, sought to sell or give away 5,000 stoves by the end of 1986, yet by the end of 1985 it had spawned a new industry whose main producers alone had sold 110,000 improved stoves at a profit. They had captured a large slice of the market previously dominated by the cheap one-unit-a-year "jikos," scrap metal charcoal stoves with a fuel efficiency of about 19%. The new stove was designed to compete directly with these traditional stoves. There was extensive local participation in the design: scrap metal artisans were consulted to make manufacturing easy, and prototypes were tested in 600 households to ensure acceptability. The final design comprises a scrap metal casing, waisted for stability, with an insulating ceramic liner, a grate in the top half, and an ash chamber at the bottom. The other main reason for success is the new stove's very favorable cost-benefit ratio: it costs more, but lasts longer than the old stove, resulting in actual savings over two years. The new stove's measured fuel efficiency is 29-30%, theoretically offering fuel savings of 34-37%, but many users report savings of up to 50% (probably due to more careful fuel use). For the average Nairobi family, the stove pays for itself within eight weeks and provides an annual return of up to 1,000% on the investment (WRI/IIED, 1987, p. 232).

8.44 The reasons for failure have varied. The driving motive of those developing and seeking to promote new stoves has usually been to save fuel, but women in the "target population" have often had a number of other, and frequently overriding, concerns which the designs proffered did not address to their satisfaction. Cultural and dietary reasons are important, as are cost, local availability of materials, convenience of use, cooking time requirements, suitability for local cooking implements

Women in some villages in Mali responded poorly to cookstove programs because they had different perceptions of their own time constraints than program planners. These women considered the time required for food preparation and cooking to be more burdensome than the time needed to collect fuel; hence, they preferred a stove that would reduce cooking time, rather than save fuel (Molnar, 1989, p. 41).

and utensils, suitability for different fuels and a variety of other factors. Women may be averse to cooking outside. The stove's capacity may be too small to cook for large families or to prepare several dishes simultaneously. Solar cookers are useless in the evening when meals are prepared. Stoves are used not only for cooking, but also heating; etc. (M. Carr, 1985,

pp. 133-134). Other important reasons for non-adoption include: unaffordable building cost; construction materials not locally available; drastic changes required in cooking habits and cultural taboos; size inappropriate to needs; design inappropriate to multiple purposes, including water heating, space heating, and smoke generation to repel insects under house roof; cooking time requirements; etc. Complications also tend to arise because it is often men who buy the stoves while women operate them (Elnur, 1985, p. 36).

8.45 It is imperative to begin stove promotion efforts with careful studies of local dietary and cooking habits and practices. It is particularly important to involve women from the start. In the Sahel, simmered stews are the mainstay of the diet, and a lot of wood is used to prepare these on a three-stone stove. Whatever replacement is recommended, it must meet a number of conditions (e.g., suitability for cooking practices, affordability, transportability, repairability, replaceability, smoke may be desirable, etc.) Examples of successful programs which have involved the targeted women from the inception of the program include: the USAID-supported Kenya Renewable Energy Development Project; KENGO's cookstove projects in Kenya (the ceramic *Jiko* and the *Kuni Mbili* stoves); the Women and Energy Project initiated in 1984 with GTZ-support by Maendeleo Ya Wanawake in Kenya; the ILO/World Bank Stoves Feasibility Project in Ethiopia which focused on urban women in Addis Ababa; the Ban-ak-Suuf stoves program in Senegal; the program in Burkina Faso based on the stove design of the Burkina Energy Institute; and the portable metal *Mai Sanki* stove in Niger.¹⁹

A promising possibility for poor and scattered rural populations is indicated by the stove program in Burkina Faso. Based on a design developed at the Burkina Energy Institute, the stove is basically a shielded traditional three-stone stove, with a circular shield or shell built of clay, dung, millet chaff and water around three stones that support the pot. A woman can build the stove in half a day to fit any desired pot size; the simple design and construction method require only half a day's training. There are no cash costs. Fuel savings range from 35 to 70 percent. Most women recoup the investment of a day's training and labor within one or two weeks through savings in fuelwood. By April 1986, some 85,000 improved three-stone stoves were in use (WRI/IIED, 1987, pp. 232-233).

8.46 For urban users, reliable, economically accessible and appropriately priced alternative energy sources, such as kerosene and liquefied petroleum gas (LPG), must be developed. Low-income urban users may need assistance with appropriate credit schemes to purchase stoves and appliances which utilize these fuels.

¹⁹ 40,000 of these stoves have been produced and sold, replacing the traditional wood stove, and users have been able to reduce their expenditure on fuelwood by 30 percent, thus recovering the cost of the stove in two months.

B. Policy and Institutional Aspects

8.47 Although environmentally benign technologies of the kind discussed above have been tested both widely and successfully in Sub-Saharan Africa, they have generally not been adopted by large numbers of farmers. The "imported" technologies involving fertilizers, pesticides and herbicides, HYVs and farm mechanization have not fared much better. The reasons for non-adoption vary, but the basic problem has almost always been a poor fit with the resources available to farmers, combined with farmers' risk aversion. Inappropriate price, tax and exchange rate policies, inadequate rural infrastructure, inefficient marketing systems, and poor agricultural support services have all contributed to keeping resources out of the reach of farmers and to increasing the risks inherent in innovation. In this situation, and as long as uncultivated land remained available for clearing and cultivation, it made sense to farmers to cultivate new land rather than to use more labor-intensive and/or financially costly production methods. This continues to be the case in much of Sub-Saharan Africa.

8.48 These problems have been more apparent with respect to "imported" technologies -- not only because these have tended to be the ones promoted most actively by governments and aid agencies alike, but also because these technologies have tended to require significant departures from familiar resource management and production techniques and in relative factor utilization. Placing greater emphasis on improving and adapting the types of techniques discussed above should considerably lower the adoption threshold. But a number of measures will be necessary to create a policy and institutional environment that is conducive, rather than inimical, to agricultural intensification and resource conservation.

8.49 Farmers require incentives and assistance to adopt yield-enhancing and soil-conserving technologies. Sustainable farming must be made profitable -- and environmentally unsustainable practices must be made unprofitable. To promote the switch to environmentally sustainable farming, the cost of resource degradation and destruction must be increasingly shifted to farmers instead of being borne entirely by society at large and, in effect, by future generations. Privatizing the social costs of resource-depleting farming practices will discourage their use. Government policy must be such as to permit farmers to profit from switching to sustainable agriculture and to incur obvious costs if environmentally destructive methods are used. The major tools for this are: (a) land tenure reform, (b) economic policy that increases the profitability of market-oriented farming, and (c) agricultural services which help farmers through the transition to sustainable agriculture.

(i) Land Policy and Tenure Reform

8.50 It is essential to ensure the security of land tenure -- to halt the erosion of security traditionally provided by customary tenure systems. Secure rights to land (individual or communal) are necessary to encourage management practices and investments that ensure sustainable use of a fragile natural resource base. Over time, population pressure and agricultural intensification will make formal land titling necessary. The administrative machinery for land titling needs to be established to permit those seeking titles to obtain them. The transition to full land titling will require more than a decade to achieve in most countries of Sub-Saharan Africa and should be undertaken only in response to demand from below, not as an imposition from above. In the interim, respect for traditional tenure systems needs to be codified. Judicial mechanisms for dealing with disputes between owners claiming traditional versus modern land rights are needed. Land laws and regulations should respect traditional tenure systems, permitting modern titles only when land is fairly purchased or acquired with the agreement of traditional owners. Women's tenurial/usufructual rights must be safeguarded, if not enhanced. Titles provided to groups for collective ownership should also

be available. Kenya has begun this by providing land titles to group-owned ranches, with groups organized by clan. French aid and the World Bank are planning to experiment with community titles in several of the Sahel countries. Governments should divest themselves of most land, except parks, to individual or community owners. This would be a first step in inducing farmer landowners to conserve the land.

8.51 Local people and communities must be given a direct and tangible interest in the sustainable management of ranges and woodlands and in the conservation of forests and wildlife. Communities cannot be effective at managing their natural resources unless their authority is clearly established and recognized. In particular, the appropriateness of statutes vesting residual control over all land in the state should be re-examined. In return for legal title, the populations of forest and range lands must accept obligations for proper management of these areas. Economic incentives to conserve could be strengthened by allocating the benefits of forests and pastures to local populations in the form of logging, hunting and gathering rights in forest areas and exclusive grazing rights in pasture areas. Opening up new land for cropping in certain areas might be subject to heavy land taxes. Only by involving the local people as partners in conservation, with appropriate incentives, will conservation occur.

(ii) Agricultural Support Services

8.52 Urgently needed are farm technology development and dissemination mechanisms that are effective: agricultural research, extension, education, and farm input supply. Each of these activities will have to incorporate the soil conservation, fertility management, agro-forestry, pest management and environmentally sustainable farming techniques identified above. There are not many of these services anywhere in Sub-Saharan Africa that are working well, and virtually none that are competent as yet in environmentally sustainable agriculture.

The success of new crop varieties introduced into Sub-Saharan Africa in the past 30 years has been limited. Rice in a few parts of West Africa, hybrid maize in parts of Ghana, Kenya, Nigeria, Zambia and Zimbabwe and, more recently, improved cassava varieties developed by IITA are among the few success stories of yield-increasing varietal improvements adopted by farmers. Productivity in tea production has increased impressively in Kenya, Burundi and Rwanda. Maize yields have increased in Benin and Gabon, and cotton has performed well in much of francophone West Africa, Swaziland and Zimbabwe. Coconut in Côte d'Ivoire, oilpalm in Zaire, and control of coffee berry disease in Ethiopia and Kenya are other examples of positive research impact on agricultural production. Yield increases implied in aggregate data for sorghum and groundnuts, on the other hand, appear to be the result of acreage reductions (abandonment of less suitable land and/or movement of unproductive farmers to other crops), rather than of technological improvements. (Lipton and Longhurst, 1985; World Bank, 1987c; 1987d; 1989d.)

8.53 Although there have been success stories, agricultural research in Sub-Saharan Africa has, on the whole, not performed well -- largely because of weak government commitment and poor management, rather than inadequate funding. Externally financed projects have not provided the needed breakthrough as yet. To develop, test and adapt technologies of the kind identified above, national agricultural research systems (NARSs) must be rehabilitated and given work programs relevant to the task. Most important will be strengthening national capacity to plan, manage and carry out research focused on the issues identified above. Both research and research management skills need to be developed. Faculties of agriculture, NGOs and the private sector should be drawn into the effort. Aid donors should coordinate their efforts so that external aid strengthens NARSs in this endeavor.

8.54 Agricultural research in and for Sub-Saharan Africa needs to focus on the conditions and constraints that prevail in Sub-Saharan Africa and that determine the production environment of

A 1987 review by the World Bank of agricultural research in Eastern and Southern Africa (World Bank, 1987c) noted that the impact of agricultural research on economic growth had been less than that experienced elsewhere because of a number of particular characteristics of Sub-Saharan Africa:

- The relative insignificance of irrigation and the large agro-ecological diversity in rainfed farming in SSA.
- The hostile physical environment (droughts, fragile soils) and the more complex systems of farming which African farmers employ to diminish risks and conserve fertility.
- The relative shortage of labor at peak periods of demand for farm labor, which makes mechanization (not necessarily tractorization) important; at the same time, trypanosomiasis raises unique obstacles to animal power in many areas.
- Inadequate macro-economic policies, which have exacerbated deteriorating world market conditions and limited farmers' incentives to adopt new technology and expand production.
- The relatively low efficiency of agricultural support services (extension, input distribution, credit, marketing, and seed production).
- The fact that small countries find it difficult to sustain both adequate agricultural training facilities and a minimum research capacity to test and adapt imported technology to an often wide range of agro-ecological conditions.

farmers in Sub-Saharan Africa. Direct application of "off-the-shelf" technology imported from other regions has rarely proved successful. As already noted, African soils need careful management, rainfall is unpredictable, the likelihood of drought in any given year is high, and dry spells may occur at any time in the growing season. Moreover, since the many different patterns of soil, elevation, slope, aspect, rainfall, temperature and solar radiation result in an enormous diversity of agro-ecological micro-environments, strong emphasis needs to be placed on location-specific adaptive research. For the same reasons, researchers need to pay far greater attention to the spontaneous experimentation and adaptation of farmers themselves – because that is where the real fine-tuning of technological innovations to farmers' complex agro-ecological and socio-economic conditions occurs (Richards, 1991; Chambers and Toulmin, 1991). The similarly vast variety of farming systems – based not only on the local agro-ecological conditions, but just as firmly on the often poorly investigated and even more poorly understood socio-economic arrangements, institutions and traditions – lends further weight to this requirement. The highly pronounced gender-specificity of agricultural tasks and entire farming systems in many communities is one important manifestation of this aspect. The parallel existence of individual and communal fields in many communities' land use systems is another. The frequent distinction between rights to land and rights to trees under traditional tenure systems is a third.

8.55 National research priorities must relate to the specific agro-ecological and socio-economic characteristics, production patterns and development objectives of each country. Each country needs to test and adapt technology under its own specific conditions, but it will take time to rehabilitate and develop NARSs and for these systems to introduce the concerns of sustainable agriculture into their work programs. Moreover, most countries of Sub-Saharan Africa are too small to undertake the entire range of agricultural research needed. Much of the basic and applied research on sustainable agriculture will therefore need to be undertaken at the International Agricultural Research Centers (IARCs) and to some extent by universities and research centers in the industrialized countries. Regional and international collaboration and African regional networks of researchers are needed to facilitate sharing of research results and experiments on the subjects relevant to sustainable agriculture.

8.56 The capability of NARSs to undertake multi-locational verification of international and national research findings on farmers' fields and the analysis of farmers' constraints needs to be strengthened. There is an urgent need to identify more intensive farming systems which can sustain soil fertility and structure and conserve soil moisture. Better integration of livestock and of agroforestry into farming systems will be important in this regard. Low-cost, low-risk techniques

found effective in similar environments elsewhere need to be tested and, if found suitable, promoted. Agricultural scientists must learn to fit their research to farmers' real situations. An intimate understanding of local constraints such as soil conditions, pests and diseases, moisture variation, seasonal labor shortages and the gender aspects of farming systems is essential. New varieties must be tested under zero- and low-input conditions and in mixed and inter-cropped situations before being recommended to farmers through the extension services. Appropriate improved drought-resistant and short-duration varieties of millet and sorghum are urgently needed. Indeed, work on these and other important indigenous food crops (roots, tubers, plantains) has long been neglected. Also neglected has been social science research which should be an integral part of adaptive research (World Bank, 1987c). Research on biological soil fertility maintenance, especially nitrogen fixation and the ecology of microbes in the soil, should complement soil conservation efforts (Brown and Wolf, 1985, p. 43).

Farming Systems Research (FSR) must pay far more attention to the importance of non-farm and off-farm activities and incomes in rural households. These are critical elements of such households' resource- and risk-management strategies. They also pose constraints and provide opportunities: off-farm work may preclude on-farm labor intensification, but off-farm income may allow cash expenditures not otherwise possible. Off-farm work is far more often recognized as important in the case of men -- notably when and where it involves outmigration (be it daily, seasonal, or long-term) from the villages. It is also very important for women -- yet often totally ignored in rural/agricultural development planning and projects. Throughout Sub-Saharan Africa, women derive important income from such activities as beer brewing, produce marketing, non-wood forest product gathering and processing, etc., and the cash income derived from such activities is often critical for family welfare.

8.57 Extension services that effectively transfer sustainable agriculture technologies to farmers are critical. Equally essential is the need for extension services to ascertain and transmit information to researchers regarding farmers' needs, problems and constraints. Farming systems research is not likely ever to succeed in covering the vast diversity of micro-ecologies of Sub-Saharan Africa or the countless permutations of crop and tree combinations that farmers use. Extension services therefore also need to facilitate farmers' own experimentation and the transmission of indigenous adaptations from farmer to farmer. If extension services are to offer farmers the best techniques to suit their specific circumstances, they must provide "menus" of options for farmers to choose from -- rather than deliver prescriptive composite "technology packages." Farmers will then experiment to adapt research findings and extension recommendations to their own specific set of needs and constraints. Extension services must collaborate with their respective NARSs in maintaining a continuous two-way flow of information between farmers and researchers and ensuring that research is geared to farmers' needs and meets the criteria of sustainability and profitability.

8.58 Given the high degree of gender-specificity in farming operations, the widespread prevalence of gender-segregated farming and the increasing incidence of female-headed households and female-managed farms, it is imperative that extension services be far more effectively oriented towards reaching women farmers. Steps to accomplish this have been initiated in a number of countries (see, for example, Murphy, 1989; Saito and Weidemann, 1990). They include: deployment of more female extension staff, properly trained and equipped; use of more female contact farmers and of women's groups to facilitate the delivery of extension messages and to obtain feedback; training of extension workers to be aware of, and responsive to, women's responsibilities, needs and constraints; and adoption of special measures to reach women farmers. The latter include, for instance, timing of visits, selection of crops and impact points, and adaptation of technology messages to women's time and resource constraints, to their production objectives and risk perceptions.

8.59 Unified agricultural extension systems are more cost-effective and appropriate to farmers' needs than the multiple subsector-specific or single-commodity services currently operating in many

countries, often supported by different aid donors. Such consolidation has been effected successfully in Kenya, Zimbabwe, Togo, Mali and Burkina Faso and is now being implemented in Ghana and Nigeria.

8.60 The content of agricultural education will need to change. It must focus on training for low-input, labor-intensive environmentally sustainable small-holder agriculture under tropical and sub-tropical conditions, rather than for high-input, mechanized farming more suited to temperate climates. This will require teachers competent in these fields as well as appropriate texts and other teaching materials. Most important, it will require refocusing agricultural education in most SSA countries and widening it to include natural resource and environmental concerns.

8.61 Research and extension services, along with private voluntary organizations, should be active in developing and testing prototypes of inputs and investment goods consistent with sustainable agriculture (new hand tools, animal-drawn equipment, crossbred cattle, village- or farm-level grain storage facilities, more efficient stoves, hand pumps, small-scale agricultural processing technology, trees for agro-forestry, organic fertilizers, etc.). These can subsequently be produced and distributed by the private sector.

(iii) Exchange Rate, Trade, Fiscal and Pricing Policies

8.62 Agricultural intensification requires that agricultural production be sufficiently profitable to induce and sustain this process. Profitability depends heavily on the policy environment which creates the incentives and disincentives to which farmers respond. Past government interventions have generally tended to turn the internal terms of trade against agriculture. Generally, the best policy has been found to be a relatively liberal market-based price system, with a fairly equilibrated exchange rate,²⁰ and open entry to marketing and processing. Price stability might be pursued in the face of international price fluctuations through a system of variable export and import duties.

8.63 There also is a need to provide positive incentives for sustainable use of natural resources and negative incentives to reduce their inefficient use and prevent their destruction. Promoting environmentally benign and sustainable agriculture may therefore require taxing of environmentally unsustainable practices. It may also be advisable for society to assume some of the costs involved in moving farmers from unsustainable to sustainable production systems -- in recognition of the socially desirable externalities involved (see para. 8.10). There may be a case for selective and temporary subsidizing of such activities as tree nurseries and seedling distribution, distribution of more efficient prototype stoves, watershed stabilization and soil conservation, water harvesting and small-scale irrigation. Conversely, farm machinery powered by fossil fuels, logging, land clearing, and fuelwood extraction from public forests and woodlands should be taxed.

8.64 Subsidies influence decisions to employ commercially available inputs (e.g., chemical fertilizers, farm machinery, seedlings). The effects of subsidies on the environment can be either beneficial or detrimental. Input subsidies compensate somewhat for low output prices received by farmers and, hence, may favor conservation -- at least on farms producing for the market. On the other hand, artificially lowering the price of inputs through subsidization may encourage the use of

²⁰ In the countries of the West African Sahelo-Sudanian Zone, exchange rate distortions make the recommended agricultural intensification and anti-desertification activities simply not sufficiently productive, below the 800 mm isohyet, to make their widespread adoption financially worthwhile. More realistic exchange rate regimes would make these techniques more attractive (Gorse and Steeds, 1987, pp. 31-32).

economically and environmentally inappropriate technologies. For instance, excessive or inappropriate use of chemical fertilizers and pesticides, stimulated by heavy subsidies, can do much environmental harm. Temporary subsidies may be justified and beneficial for environmentally benign inputs – to popularize a new technology. But in the long term, subsidization of any input is difficult to justify.

8.65 Subsidies for basic anti-erosion activities (especially engineering measures) are frequently advocated – but where such policies have been implemented, they have often had very undesirable effects. Lack of subsequent maintenance, lack of local identification with the effort, and disruption of local incentive systems (e.g., wage labor markets, investment versus maintenance attitudes) have been the most common and serious problems. Moreover, as noted above, engineering measures are rarely sufficient by themselves and must be combined with changes in on-farm soil and water management practices; these latter are often ignored when attention is focused on engineering works and subsidy administration. Finally, engineering is costly and is rarely the most effective technique. Even if subsidies are to be considered for such initial investments (and there are common investments that may be needed, such as runoff evacuation channels and water storage/harvesting structures), subsidization must be carefully thought through in all its consequences.

(iv) Local Institutions: Involving the People

8.66 If farmers are to innovate and adopt sustainable agricultural production and resource management techniques, they need to be given more responsibility for their own affairs. They should be allowed to associate freely in farmer-managed cooperatives and groups, to market their own produce, to own and manage their land. Tenurial security must be ensured. People will only cooperate in environmental resource conservation efforts if they have a stake in the resources to be conserved and incentives to manage their environment more prudently. Administrative regulations will not suffice – even if enforcement mechanisms were to be substantially strengthened. Responsibility and authority to manage range land should be vested with pastoral associations. Forest dwellers should be given responsibility to manage the forests where they live and where they should be assured of priority, or even exclusive, rights to hunt, gather and carry out artisanal logging. In return, they should be entrusted with the obligation and requisite authority to protect these forests against farmer encroachment, poaching and illegal logging and fuelwood extraction. If the state is less intrusive and local people are given greater responsibility, people will tend to take more care in conserving their environment (presuming that the other actions discussed here are also taken).

8.67 Resource management interventions must emphasize the social arrangements among people as they interact with each other and their natural resource base, with particular attention to incentives and sanctions for influencing individual behavior. "[Every] aspect of the inter-relationship between society and nature plays a critical role and if one of them fails then the whole situation is likely to be severely affected" (Timberlake, 1986, p. 42). Natural resource projects that do not actively involve the local users will fail. National, and even regional, governments cannot effectively manage local natural resources. The sheer scale of the soil and water conservation problems faced in many countries dictates the need to create the necessary conditions for local people and communities to take matters into their own hands again. Programs and projects must become more concerned with the people using natural resources and less preoccupied with the commodities around which projects have traditionally been organized. An essential ingredient in program and project formulation and implementation is the existence of incentives and sanctions for influencing the individual behaviors of those who live in the area and who depend for their livelihood and survival on the natural resources in question (Bromley and Cernea, 1989).

8.68 Traditional land and natural resource management systems may not have been ideal, but their subtleties need to be realistically assessed. There is the danger that overzealous, well-meaning efforts will destroy an imperfect but functioning system, only to find that the substitute hardly functions at all. Pilot operations in land management are already under way in a number of countries and hold promise of success. The existence of pastoral associations in Senegal and Niger, village land management and water conservation efforts in Burkina Faso and the *comités du village* in Mali have demonstrated that careful attention to the needs and practices of local people can generate enthusiasm for positive action in rural areas. These examples suggest that some governments are beginning to have the political confidence to relinquish control over resources to local groups as well as the political determination to enact legislation that will support such initiatives. They also show that local communities can improve their situation when they believe their efforts will pay off (Falloux and Mukendi, 1988).

8.69 Whether governments will be willing or able to recognize or create centers of authority and initiative in rural areas remains to be seen. Some governments are already making firm commitments in that direction. Smaller organizational units, such as village or pastoral associations, are better equipped to manage their own resources. Recognizing this is a prerequisite for implementing the strategies aimed at improving production systems and land use. These local associations might provide a far more effective basis for rural development and rational resources management than many other previous efforts which imposed external institutions on rural societies. Group action is deeply rooted in most societies of Sub-Saharan Africa – for managing land, for cooperative marketing and input supply, for pooling savings and financing credit, for pooling labor for critical tasks at critical times. To succeed, cooperation has to be voluntary and managed from below. Grassroots management is one way to assure this. Alternatively, cooperatives can be based on customary social structures and groups, as they often are. Governments can provide technical assistance, such as advice on accounting, legal rights, and technology, and should provide for legal arrangements that facilitate the creation, recognition and dissolution of cooperatives.

8.70 What is most needed is popular participation and action at the village and community level, using and developing local skills and responding to the particular characteristics of each area. This is the single most important lesson that has been learned (Shaxson *et al.*, 1989, pp. 12-14). Identifying concrete practical mechanisms to foster popular support is critical. Grassroots organizations and local NGOs have a particularly valuable role to play in this respect. Channeling financial resources, to the extent these are needed, to and through them is important, but more important will be meeting their urgent need for institutional strengthening and training in such critical areas as program planning, management and leadership skills, accounting, financial planning and management, and information sharing (Newman, 1992). Governments, international aid agencies, and international NGOs alike will need to find ways to provide this critical support.

IX. INFRASTRUCTURE DEVELOPMENT, MIGRATION, AND URBANIZATION

A. Infrastructure Development

9.1 The most basic elements of rural physical infrastructure comprise rural roads, markets in rural towns, and rural water supply facilities. In certain areas, irrigation and drainage facilities would also be essential to facilitate agricultural production. At a somewhat higher level of development, it also includes rural electrification as well as telecommunications facilities and access to electronic mass media. Defined more broadly, rural infrastructure also includes educational, health and sanitation facilities. Given the critical importance of such facilities -- or, more importantly, of the services they provide -- for the development and maintenance of "human capital" in rural areas, these are indeed crucial in the context of the Nexus.

9.2 The importance of basic rural infrastructure for agricultural development is well established. Recent research in Asia found that in villages with better infrastructure, fertilizer costs were 14 percent lower, wages were 12 percent higher, and crop output was 32 percent higher (IFPRI, 1991). No comparable analysis is available for Sub-Saharan Africa as yet, but similar findings would be likely. Research in a number of SSA countries has shown that adequate transport links to product markets stimulate agricultural intensification -- even where population densities are comparatively low (Pingali *et al.*, 1987). Farmers with access to good infrastructure use land more intensively, adopt efficient techniques and modern inputs, produce more for the market, and employ more labor.

9.3 Infrastructure development also has a major impact on the productivity of rural labor and on key determinants of fertility, such as infant mortality and female education. Roads provide access to health facilities and schools, and water supply schemes and sanitation facilities have significant impact on health and on labor productivity. Education, health, water supply and sanitation facilities and services are particularly important in terms of their impact on female education and on infant and child mortality -- both critical determinants of fertility preferences (see Chapters III and VII).

(i) Transport

9.4 Transport infrastructure is essential for intensifying agricultural production. Remunerative output prices accelerate the pace of agricultural intensification -- provided they are transmitted to the farm. Incentives to increase production and marketed output are blunted if the physical barriers and, hence, the costs of moving goods to and from local markets are too high. This is equally true of the national transport system linking local markets to cities and to ports.

9.5 Rural transport infrastructure in particular is highly deficient in most countries, and throughout most of Sub-Saharan Africa distances from villages to major towns and all-weather roads are substantial. Rural road density has been estimated at about 32 m/km² in Western Africa and 36 m/km² in Eastern and Southern Africa. Moreover, Nigeria, Cameroon and Côte d'Ivoire account for more than half the rural roads in Western Africa, and Tanzania, Zaïre, Zimbabwe and Madagascar have more than two thirds of the rural roads in Eastern and Southern Africa between them (Riverson, Gaviria, and Thirscutt, 1991, p. 4).¹ In Nigeria, with its fairly dense network of

¹ Of course, rural road densities also vary considerably within countries, being generally higher in areas with higher population densities and productive natural resource endowments. In Kenya, for example, rural road density ranges from 400-500 m/km² to less than 30 m/km² (Riverson, Gaviria, and Thirscutt, 1991, p. 4).

rural roads by African standards, rural road density today is about 90 m/km², barely equal that of India in 1951; a reasonable target density, based on Indian areas with comparable population densities would be 730 m/km² (*ibid.*). Where rural roads exist, they often are poorly maintained. Indeed, maintenance standards have deteriorated considerably during the 1980s: 42 percent of unpaved roads in West Africa and 47 percent in East Africa were in poor condition in 1988, compared with 28 percent and 44 percent, respectively, in 1984 (Carapetis, Levy and Wolden, 1991a, p. 12).

9.6 The availability and reliability of transport services is often further compromised by restrictive transport sector policies and trucking regulations. Transport monopolies, for example, are often granted to parastatal companies or to well-connected individuals, and entry into the industry is often restricted even where there are no monopolies. Inefficient procurement and distribution of motor fuels by monopolistic parastatals is often another impediment. And price controls on motor fuels tend to reduce fuel availability in the countryside because they make it unprofitable to invest in transporting and selling motor fuels in locations distant from the port cities.

9.7 As a result, markets are poorly integrated, inter-regional and inter-seasonal price variations are far greater than they would be in the presence of efficient transport facilities, and incentives to switch from subsistence to market production are often weak. Where there is surplus farm produce, it often has to be carried over considerable distances to markets or to roadsides from where vehicles can move it to processing facilities and/or consuming centers. Women bear the brunt of the rural transport burden since much of rural commodity transport (water, fuel, farm inputs and farm produce) is done in the form of headloading by women. Studies throughout SSA show that women and older girls carry loads of 10-25 kg (sometimes as much as 40 kg) and can manage 3-5 km per hour, depending on terrain and load weight.

9.8 Rural roads and improved tracks navigable for animal-drawn vehicles are crucial for rural development. Planning, construction and maintenance should involve the local communities as well as local contractors and technicians. This will help ensure that siting is in accordance with local needs, make maximum use of labor-intensive techniques to keep down costs, and provide local off-season employment.

9.9 Major efforts are also needed to promote the use of locally appropriate intermediate means of transport (IMT),² especially animal-drawn implements, and off-road transport.

Rural Transport in Ghana

A field study in the Ashanti, Volta and Northern Regions of Ghana (Barwell *et al.*, 1987) found walking and headloading to be the predominant means of rural travel and transport. Transport activities for an average household, numbering 11.4 persons, involved an average of about 4,800 hours (with a range from 3,740 to 6,210 hours) per year and a load-carrying effort averaging 234 ton-km per year (ranging from 185 t-km to 315 t-km). This comprised 54 t-km water fetching, 20 t-km firewood gathering, 75 t-km crop harvesting, 77 t-km crop marketing, and 8 t-km produce carrying to and from the local food grinding mill. About three quarters of the load-carrying effort involved and of the time spent concerned transport within and around the village.

Women accounted for about three fourths of the total loads carried. The average adult woman spent 977 hours per year, or 19 hours per week, on transport activities, mainly headloading. This involved water carrying (11.8 t-km per year per woman), crop harvesting (13.1 t-km), crop marketing (14.7 t-km), fuelwood collection (5.0 t-km), and food processing (2.0 t-km). Male involvement in transport was far less, about 346 hours per year per adult male, and was almost entirely crop-related (harvesting, 7.9 t-km; marketing, 2.9 t-km), with little involvement in transporting water (0.8 t-km) and fuelwood (0.5 t-km).

² IMT refer to technology intermediate between walking and headloading on the one hand and motor vehicles on the other. They cover a wide range: improved aids for human portage (shoulder bars, yokes, backpacks), panniers and rigs for pack animals, animal-drawn sleds and wheeled vehicles, wheelbarrows and handcarts, bi- and tricycles and trailers, etc.

Governmental involvement in these areas would have to be largely facilitative and promotional. Improvements in off-road transport are essential for rural people's wellbeing and productivity. The extremely poor state of off-road transport in much of Sub-Saharan Africa severely reduces the timeliness and quantities of agricultural inputs and outputs moved to and from motorable roads, thus acting as a strong brake on agricultural productivity and growth (Riverson, Gaviria, and Thiriscutt, 1991; Riverson and Carapetis, 1990). Rural women in particular will benefit very considerably from such improvements – with significant follow-on benefits in terms of the various Nexus linkages.

9.10 Farmers also need information about technical options and market opportunities. Improved communications more generally are required, including not only transportation but also telecommunications and access to electronic mass media. The latter also have significant potential for reaching rural populations with health and educational information, including information concerning family planning and the prevention of sexually transmitted diseases.

(ii) Water Supply

9.11 The rural water supply situation constitutes another key constraint -- and an important link in the Nexus. Less than 20 percent of Nigeria's rural population, for instance, have convenient access to safe water. There is a direct link between safe potable water and the reduction of infant mortality, and efforts to provide safe water and sanitation facilities have been motivated mainly by these and other direct health considerations. Water-borne and water-related pathogens are major causes of seasonally or permanently debilitating diseases which severely effect, *inter alia*, labor productivity, and often especially during periods of peak demand for farm labor (e.g., land preparation and planting).

9.12 Women's stake in convenient access to safe water and sanitation facilities is particularly high, given their almost exclusive responsibility for collecting, transporting, boiling and storing water for drinking and cooking and for washing household effects and laundry, for disposing of waste water, and for maintaining household sanitation standards and facilities. Women have to determine the water sources that can be used for various purposes (for drinking, washing, cooking, watering domestic animals and home gardens, etc.); collect, transport and store the water; and purify drinking water using simple techniques and locally available materials (Dankelman and Davidson, 1988, p. 32). In rural Kenya, 89 percent of the women over age 14, but only 5 percent of the men, reported fetching water as one of their normal tasks; the same percentages were reported for fetching fuelwood (Republic of Kenya, 1980). Access to sufficient quantities of quality water is an increasingly more time-consuming problem for many rural women. A study in Kirinyaga, Kenya, found that 70 percent of trips that involve carrying a load are for fetching water (Kaira, 1982).

9.13 Assuming a daily requirement of, say, only 10 liters of water per person, a six-member household needs 60 liters of water daily -- almost 22 tons of water each year. If a women carries 20 liters of water per trip (provided she has the appropriate vessels), this implies that she would have to make three trips daily to the water source -- or have her daughter(s) help her with this chore. If the water source is 20 minutes away from the home, about 2 hours daily will be needed to meet the household's water needs. If young girls are responsible for fetching water, they carry less weight and, hence, will need to go more often. The work load increases substantially if water also needs to be brought home for watering domestic animals and/or the home garden, brewing beer, processing cassava, making mud bricks, or other production tasks requiring water.

9.14 Drastic changes in the rural landscape brought about through deforestation, in many areas exacerbated by prolonged drought, have made water far more difficult to obtain. Springs, streams

and rivers run dry for long periods, and wells go dry as the water table recedes. The 1976-79 Integrated Rural Surveys of Kenya found that during the wet season 48.8 percent and during the dry season 56.1 percent of all rural households were more than 1 km from their sources of water; 14.2 and 22.8 percent, respectively, were more than 2 km from their water source, and 1.4 and 3.0 percent were more than 5 km from the nearest water source (Republic of Kenya, 1980). In some areas, water sources have become polluted or contaminated. In Zimbabwe, for example, women used to obtain water from wells in the fields where they worked, but the water has become contaminated by the fertilizer used on the fields (Nyoni, 1985, p. 55).

9.15 Convenient sources of safe water are of enormous importance to improve human health and, hence, labor productivity, and to contribute substantially to a reduction in infant mortality and child morbidity and mortality. A major benefit to women and girls of better access to safe water is that time formerly spent fetching water from distant sources and preparing such water for human use can be used instead for other productive activities, attending school or technical training, tending to children's health and educational needs, or simply rest and recuperation. Water supply efforts/projects must be planned and implemented, if not operated, with and by local women.

Good examples of successful water supply projects based on women's groups are those of the Kenya Water for Health Organization (KWAHO), an NGO consortium supported by the government, UNDP, UNIFEM and the World Bank. In Kwale district, it has organized cooperative handpump installation and maintenance with female extension workers, village decision-making, local materials and labor, backed by training in health, water use, pump maintenance, bookkeeping and group organization (Dankelman and Davidson, 1988).

(iii) Infrastructure and Environmental Conservation

9.16 Infrastructure development is a major determinant of the way people use land as well as of the spatial allocation of people on land. Sound infrastructure policy is therefore a powerful instrument in the two-pronged strategy to intensify agricultural production and to limit further destruction of forest and pasture areas. The development of infrastructure tends to attract and retain people. The many instances of colonists invading forests via abandoned logging roads provide a powerful illustration. Conversely, the absence of infrastructure in areas that are environmentally delicate will tend to induce people to stay out of those areas. Careful locational targeting of infrastructure development can guide spontaneous population movement into environmentally robust/resilient areas with agricultural potential, and into secondary towns and cities, and help keep migrants out of areas that should not be opened up to farming.

9.17 Infrastructure development, and especially road construction, should therefore be focused where the potential for agricultural intensification is highest and/or where settlement is to be encouraged. It should be avoided in forest areas which are to be conserved and in other environmentally fragile areas where an influx of people will lead to environmental degradation and destruction. Concentrating infrastructure development and thereby attracting/retaining people in areas of high production potential and keeping them out of environmentally fragile areas also allows considerable efficiencies in investments and service provision, since the per capita cost of infrastructure development and maintenance is inversely related to population density.

B. Migration and Settlement Policy

9.18 Given the considerable agro-ecological diversity in most countries of Sub-Saharan Africa, the development and adoption of suitable productivity-enhancing and environmentally appropriate agricultural technology will of necessity be highly region- and even location-specific. This will, over

time, engender significant regional disparities in agricultural production and income growth. Governments will need to resist the urge to correct for this by targeting scarce public resources to the lagging regions. Allowing, facilitating and encouraging migration from the lagging to the thriving regions is the appropriate policy response. This is particularly important when the lagging regions are likely to be those that have less agricultural potential and are environmentally more fragile.

9.19 In many areas, therefore, part of the solution to the problems of unsustainable agriculture and environmental destruction will of necessity have to involve some movement of people. This is the case, for example, in much of the Sahelo-Sudanian Zone where movement should be encouraged to the Sudano-Guinean Zone further south as well as to areas within the Sahelo-Sudanian Zone itself that can still absorb more people. Nigeria's "middle belt", for instance, remains relatively underpopulated, compared with the country's northern and southern regions, and holds considerable as yet untapped potential for agricultural development. The same is true for much of Ghana's Brong-Ahafo and Northern Regions.³

9.20 Many factors influence migration. Migration is multisectoral in nature and, in the context of rural Sub-Saharan Africa, closely linked to the problems of rising population pressure, land tenure uncertainties, poor land use and environmental resource degradation. Large scale migration within and between African countries is inevitable in the future, given rapid population growth and the limited absorptive capacity in many rural areas. Without strengthening tenurial arrangements to provide greater security, it will be as difficult to channel migration and settle migrants as it will be to protect and improve their host environment. A sound migration policy must consider the land-use rights of farmers, transhumant pastoralists and forest dwellers. Migration can be used as a positive development tool -- if it is linked to a well conceived settlement program. In many cases, migration can balance resource demand with resource availability. Regional surveys of migration, both quantitative (who, how many, from where, and to where) and qualitative (motivations and aspirations) should be carried out in the most sensitive areas of immigration. Without land rights that are confirmed by both custom and law, migrants have no incentive to protect or restore their land. Neither will the residents be able to protect themselves and their resource base from incoming migrants (Falloux and Mukendi, 1988). This has happened in Côte d'Ivoire, for instance, where massive unplanned immigration of Sahelian farmers into open-access forests has contributed to rapid forest destruction, widespread land disputes, and a lack of incentives for farmers to conserve the land.

9.21 Redistributing population -- to reduce pressures on the environment on the one hand and to accelerate the transition to intensive farming on the other -- requires identifying areas of high agricultural and economic potential, improving infrastructure and services (roads, water supply, schools, health facilities, markets) in these areas, and encouraging people to move to the high potential areas and into rural towns and secondary cities. Governments should normally include population distribution as a part of their policy to accommodate population growth. Spontaneous movement of people has been occurring for a long time, both within countries and across borders, in search of a better livelihood, in pursuit of trade, and to find seasonal or permanent employment. Cross-border movement has helped to ease population pressure in the areas from which people emigrate -- such as the Sahel or Rwanda. But such movements have sometimes been restricted or reversed because of political and ethnic conflicts. Benefits of population migration certainly accrue to the individual migrants and often to the communities from which they migrate. There often also are significant economic benefits for the communities receiving the migrants. The Sahelian farmers

³ In both cases, as in other countries, ethnic diversity and land tenure issues help explain the uneven population distribution.

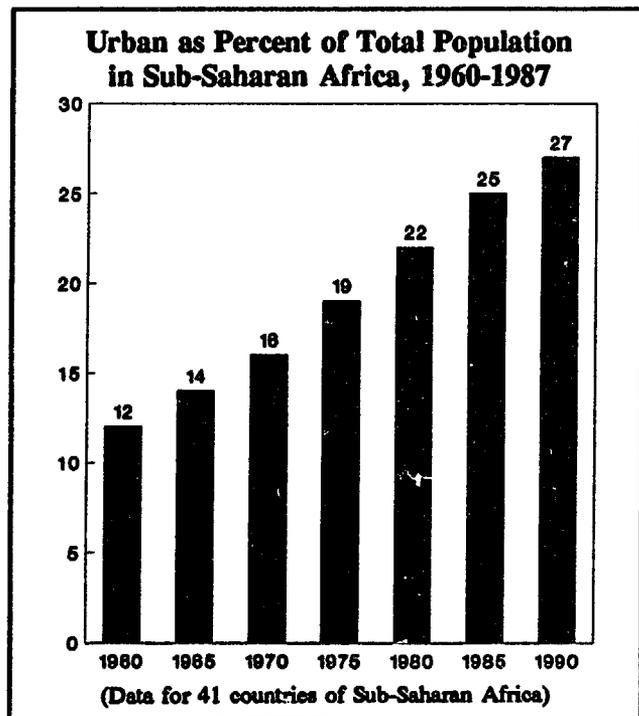

settling in Côte d'Ivoire have been a dynamic force for agricultural growth. The benefits and costs need to be realistically assessed, and migration, though better planned, allowed to continue. It is also consistent with Sub-Saharan Africans' desire to encourage and promote regional cooperation.

9.22 There are two main types of rural-rural migration: spontaneous and uncontrolled migration, and government-sponsored organized migration and resettlement. Spontaneous migration involves no direct costs to the public treasury. It is quick for the individuals who move, but in most cases takes place gradually enough to preclude social and economic upheavals in the receiving areas. Unfortunately, it also often tends to lead to poor land use practices, because migrants bring with them only the farming and land use experiences and traditions from the area they left, and these are often inappropriate to their new environment. This is particularly the case where settlers invade forest areas opened up by loggers (see Chapter VIII). Organized migration, on the other hand, usually entails high costs and is characterized by slow implementation.⁴ It, too, has often resulted in poor land use, as planning and implementing agencies have tended to promote settlement, resource use and production patterns that were poorly matched to the settlers own needs, perceptions and capabilities.

9.23 The required strategy, therefore, lies somewhere between these two. It should channel, train and support migrants, combining incentives for and controls over land use practices with the development of sustainable and viable production systems. It makes far more sense for governments to promote and support spontaneous migration and settlement, rather than to undertake organized colonization schemes. It will be critically important to devise and implement enforceable land-use regulations to promote sustainable settlement.

C. Urbanization

9.24 During the past three decades, the urban population of Sub-Saharan Africa has been growing roughly twice as fast as its total population; in a number of countries the rate of urbanization has been considerably faster still. The rate of urbanization has been especially high in west, central and east Africa, comparatively more modest in southern Africa (Montgomery and Brown, 1990, p. 76). The rapid growth of cities is due not only to the persistent high fertility rates still observed among urban women in Sub-Saharan Africa, but in large part to the very high rate of rural-urban migration. This "land-flight" is caused in part by the strong urban biases inherent in most countries' economic and investment policies. However, experience throughout the world suggests that urban populations have grown and will continue to grow much faster than rural populations – even if governments were to pursue policies that do not favor urban over rural dwellers (Cour, 1990).

⁴ For an interesting analysis of migration in Rwanda, see Olson (1990).

9.25 Some countries have pursued policies that have led to the emergence of numerous and geographically dispersed secondary cities and rural towns closely linked with their surrounding rural areas (e.g., Cameroon, Côte d'Ivoire, Cameroon, Kenya, Nigeria, Togo). They also have a few very large cities (notably Abidjan, Nairobi, Lagos, Ibadan), but urbanization in these countries has also been characterized by the development of many smaller cities and rural towns throughout much of the national territory. This has had important positive effects on agriculture. These towns and cities have created non-agricultural employment opportunities for some of the rural population, but this industrial and service sector development has been much more closely linked to agriculture as such and to the needs of rural populations. Cash remittances to home villages are an important source of financing of both consumption and investment expenditures in rural areas. Urban growth creates expanding markets for farm products and tends to lead to increased supply and availability of farm inputs and services. This can make agriculture more profitable -- provided there are adequate transport links and marketing arrangements. Where networks of rural towns and secondary cities exist, these links are far more direct, immediate and efficient. Spread-out rural towns and secondary cities tend to be associated with far greater penetration of rural areas with adequate transport links and marketing arrangements than are distant mega-cities. For areas that are approaching the limits of sustainable agricultural land use under existing tenurial, technological and climatic conditions, migration to these secondary towns and cities reduces the population pressure and provides an important safety valve.

9.26 Where government policy discourages agricultural production and encourages agricultural imports to supply urban needs, there will be no positive impact of urbanization on agriculture. This has tended to be the case in countries where urban development policy has focussed heavily on the capital or on a few dominant cities, inevitably more distant from rural hinterlands. Manifestations of such policy and expenditure bias are the subsidization of consumption of urban populations (often based on imported food), preoccupation with large urban infrastructure projects, and focus of social expenditures in a few cities. The political influence of growing, massed and vocal urban populations results in political pressure to keep food prices low and to target public investments and services disproportionately to the big cities. Where governments have effectively resisted this pressure, the results have been positive for agricultural profitability and growth: Kenya, Ghana, Togo and Zimbabwe are cases in point. Furthermore, cities often draw the most talented, enterprising and educated people from rural areas. When there are no rural towns and secondary cities to go to, these people flock to the mega-cities and their energies, enterprise and talents are lost from the rural areas. Less talented and less educated farmers are less likely to be innovators and more likely to be steeped in increasingly destructive traditional farming and land use practices.

9.27 In much of Sub-Saharan Africa, rural out-migration involves predominantly young men (Russell, Jacobsen and Stanley, 1990a). Where policy has a heavy urban bias, this has been particularly pronounced. As women, children and the old stay behind, farm management is increasingly left to women who already have multiple and very heavy responsibilities and work loads and are facing considerably greater constraints in access to resources and services than men (see Chapter V). Many rural areas are today characterized by severely imbalanced gender ratios in their adult population, with women substantially outnumbering men. In addition, if the migrants abandon resilient and productive areas in pursuit of urban employment and in response to anti-agricultural policy biases, this has a negative impact on agricultural production and rural development in the areas which they leave.

9.28 A recent analysis of farm-nonfarm linkages in rural Sub-Saharan Africa found that each US\$ of increased agricultural income generated an additional increase of US\$ 0.5 in non-agricultural

rural incomes.⁵ The direction of causality was largely agricultural growth stimulating services and manufacturing. This is less likely to occur when biased policies retard or prevent the development of secondary towns and cities and instead cut off rural areas and agriculture from the mega-city and make the latter more dependent on imports.

9.29 Considered in the context of the Nexus, urbanization is both a result and a cause of environmental resource degradation. People leave rural areas when they can no longer make a living there (or at least not year-round). Urban dwellers, especially the vast numbers of poor, require fuelwood and food. Urbanization concentrates demand at specific locations. The heavy concentration of urban populations in a single capital city (often a seaport, rather than in a central inland location) makes things worse. Huge concentrations of people in a single location, coupled with high transport costs for domestically produced supplies, result in situations where importing food is cheaper and easier than obtaining it from domestic producers. Government policies in most of Sub-Saharan Africa tend to keep food and fuelwood prices low, reducing incentives for intensification of local food and wood production. Food imports, often sold at subsidized prices, further undermine the incentives for domestic producers. They can also lead to major changes in consumer preferences that may not only diminish demand for local products, but may also be nutritionally undesirable. Fuelwood suppliers, responding to the dual opportunities presented by large concentrations of demand and virtually free access to the raw material base, mine the forests and woodlands around the cities and along roads (e.g., Gorse & Steeds, 1987, pg. 7).

9.30 The net impact of rapid rural-urban migration on the environment and on agriculture is impossible to determine *a priori*. In some countries, the positive effect will offset the negative; in others, the reverse will be true. Ensuring that urbanization has positive impact on agricultural development and environmental resource conservation requires economic policies that do not discriminate against rural areas (i.e., no price and investment discrimination), good education in rural areas, effective agricultural extension to maintain rural talent, efficient ministries of agriculture providing useful services to farmers, and considerable decentralization of decision making to local people and communities to avoid excessive dominance of the cities and their populations in national political decision making.

9.31 Greater focus on secondary cities and rural towns, in infrastructure investment and urban development generally, and a reduced bias to invest in the mega-cities, will provide a beneficial rural-urban link. Considerable synergies can be tapped here. The examples of Cameroon, Kenya and Togo show that rapid urbanization tends to occur in secondary cities and rural towns (rather than in mega-cities) if governments effectively implement policies to promote agricultural development and rural growth (Becker and Morrison, 1988). Agricultural growth is an essential lever to stimulate non-agricultural investment and growth as well as to influence population distribution. Sound urban policy is an important element to assure balanced urban and rural development, favoring rural towns and secondary cities compared to mega-cities.

⁵ Of this additional rural income, only about 20 percent was attributable to production linkages, but about 80 percent to consumption linkages. These strong consumption linkages are likely to have significant positive effects on the real incomes of the rural poor -- given the importance of female-dominated food processing and beverage production and of service and manufacturing activities with low investment requirements. They are also likely to stimulate production of fruits, vegetables and meat and, thus, agricultural intensification and diversification into higher-value products, with positive effects for rural income equity where, if, and as long as these commodities are produced by smallholders and pastoralists. The production linkages of increased agricultural incomes on rural equity depend heavily on the respective rates of growth of demand for agricultural wage labor and for purchased inputs, both of which are currently at very low levels (Haggblade and Hazell, 1988; Haggblade, Hazell and Brown, 1989).

9.32 The elements of sound urban development policy include relatively more public expenditure in secondary towns and cities and less in the largest cities than has generally been the case to date, and spatially well distributed infrastructure investment throughout the country (not merely in the largest cities). It also requires market-based petroleum pricing to promote the development of efficient transport fuel distribution systems throughout each country (para. 9.6). It will include the promotion – through industrial extension as well as fiscal and credit policies – of small and medium industry. And it will include greater community control over urban resources: given adequate financial resources and the requisite technical and administrative assistance, local and community governments are far more likely to create and maintain appropriately scaled and sited urban infrastructure facilities than are central governments. Investment in urban development should be responsive to demand for such investment, not driven by political considerations.

X. ENVIRONMENT AND NATURAL RESOURCES

A. Production versus Protection

10.1 The environmental issues that are linked to population and agriculture are primarily those involved with soil, water and vegetation. There are, of course, many other environmental problems facing Sub-Saharan Africa -- such as over-fishing in coastal waters, oil spills, dumping of hazardous wastes, pollution from urban sewage and industrial waste, land devastation from surface mining, and so forth. These problems are not, however, so closely related to rapid population growth and agricultural stagnation and therefore are not dealt with here.

10.2 Governments must be more determined in developing and implementing environmental policies aimed at: (a) maintaining and restoring, in the face of increasing consumption demands, the soil, water, pasture and forest vegetation on which agriculture will continue to be based, and (b) preserving ecosystems and plant and animal species -- both as repositories of genetic diversity that may underlie future production of many types of products, and as a national and global heritage. Solving the population and agricultural aspects of the problem are crucial to curtailing degradation of the natural environment. Agricultural intensification, farm forestry and fuelwood programs, and sensible land tenure reform are critical factors, as discussed in Chapter VIII. However, moving from the present situation of rapid deforestation and land degradation to one of stabilizing the area under trees, raising the efficiency of fuelwood use and preserving most of the remaining wilderness areas will require an "affirmative action program" of considerable consequence comprising a number of elements beyond those noted in Chapter VIII. These additional elements are outlined below.

10.3 Intensive human exploitation is inconsistent with maintenance of natural ecosystems. Despite the considerable interest and optimism often expressed with respect to sustainable exploitation of natural forests, ITTO has estimated that only one fifth of one percent of the world's natural tropical forest areas are currently being harvested on an ecologically sustainable basis (Goodland, 1991, p. 14; Poore, 1988, 1990). Even logging systems based on selective removal of certain species and age classes of trees may seriously disrupt the ecological balance of a tropical forest and destroy a significant portion of the remaining vegetation during the process of extraction. Recovery of the ecosystem can only be assured if the damaged area is very small and is surrounded by large areas of undamaged forest that can serve as a reservoir of recolonizing species. Thus, even though the area may remain forested, any type of commercial logging in a tropical forest may result in a fundamental and quite possibly irreversible degradation of the original ecosystem. This is in contrast to the less diverse and more resilient temperate forests, which can be logged productively on a sustainable basis (World Bank, 1991b).

10.4 A first step in environmental policy is to determine which areas should and can be maintained as protected areas, and which should be developed for production (agricultural, forest, livestock, fisheries). Criteria for selecting natural ecosystems for preservation include:

- (a) **Biological importance, i.e., species richness and uniqueness: the greater the importance, the more important the need for full protection;**
- (b) **Current status, i.e., whether or not the ecosystem is already degraded or spatially constricted to an extent where it is no longer stable and wildlife populations are no longer viable: the less viable a particular ecosystem, the less viable would be a decision to protect it fully;**

- (c) **Likelihood of success of preservation -- which depends on the type and degree of present threats (such as human population pressure) which reduce the likelihood of success versus the potential for supporting non-exploitative economic activities (such as eco-tourism) which increase the likelihood of success;**
- (d) **Productive potential if converted to other uses such as cropping or livestock production: the greater the productive potential under alternative uses, the less viable the decision to protect fully;**
- (e) **Provision of "environmental services" by a protected area, such as control of soil erosion, prevention of flooding, recharge of aquifers, maintenance of river flow, provision of breeding grounds for marine life, etc.: the greater the value of such services, the greater the importance of protection;**
- (f) **Importance for the survival of indigenous peoples and their livelihood systems, especially of forest dwellers: where indigenous peoples depend for physical and/or cultural survival on an area remaining undisturbed, the need for protection becomes imperative.**

10.5 These criteria imply trade-offs, and in many cases they will involve the need to make difficult choices. If one basic objective is to limit the decline in Sub-Saharan Africa's total wilderness areas (from their present extent of 27 percent of the total land area to not less than 23 percent), these criteria will need to be applied with considerable stringency. Since natural resource systems, including forests, have multiple uses, there can be no substitute for planning. Land use plans should identify conservation areas, parks, areas designated for sustainable logging, farming areas, pasture and range land, as well as areas needed and suitable for human settlements and physical infrastructure. Agricultural technology is location-specific in its applications, and land use plans therefore should identify, in broad terms, the appropriate technologies. Land tenure issues and fuelwood problems also are location-specific -- as are many of the cultural factors that help determine human fertility. Regional plans should define these, with greater weight attached to resource conservation than in the past.

10.6 Past attempts at land use planning, regional planning and integrated rural development programs have generally not worked well in most of Sub-Saharan Africa. Among the chief causes suggested by analyses of the reasons for this poor record were excessive complexity of such plans, lack of governmental capacity to prepare such plans, even greater lack of capacity to implement them, and frequent lack of incentives to cooperate for the people living in the areas concerned. Land tenure issues, identification of appropriate agricultural technology, participation by local people and private agents, and provision of adequate financial incentives were usually completely neglected. Instead, almost universally applied were engineering "solutions," with implementation entrusted to public sector agencies or donor-guided project management units. A new approach is needed for both planning and management.

10.7 Local populations must be active participants in both planning and implementation of land use plans. This is best accomplished by ensuring their ownership of the land and of the natural resources associated with it. Ownership provides the strongest and most direct incentive to conserve. Loss of ownership, or ambiguities concerning ownership, creates incentives to exploit without regard to sustainability and provides no incentives to invest in resource conservation or productivity enhancement. Governments should therefore divest most (though not all) forest and range areas to local people and assist them, through forest and agricultural services, to manage these resources properly (as discussed in Chapter VIII). Traditional owner/user communities could obtain group title.

Management plans should be prepared in a collaborative manner by the local communities, government agency staff and, where they exist, grassroots organizations and NGOs. Participatory rural appraisal (PRA) techniques provide very effective tools to do this.¹ Such management plans would provide for industrial and artisanal wood harvesting on a sustainable basis (specifying concession fees, taxes, etc.) and for essential infrastructure development and would identify areas suitable for crop and livestock production. Local populations would utilize the forest and woodland resources for fuelwood and artisanal forestry, for hunting, and for harvesting of non-wood forest products, the arable land for cropping, and the range and grazing land for livestock production.

10.8 Incentives are far more likely than governmental regulations, controls and enforcement to be effective tools for conserving natural resource stocks. The most important incentive to ensure resource conservation would be resource ownership: the certainty that resource degradation will be a cost directly borne by the current owner/users and by their descendants -- i.e., by the present and future members of the group. A second incentive will be provided through the accrual of direct income from rents and royalties for use rights concessions awarded to others. A third will be the holding of exclusive user rights.

10.9 Governments should focus their direct management efforts on a much smaller share of the total national land and forest resources -- i.e., those areas that provide public (and global) benefits and goods. This will consist mainly of parks and other protected conservation areas where there are important externalities that local populations cannot be expected to finance or otherwise support. Even there, local participation will be necessary, however, with local people given incentives to conserve the existing resource base of the protected area through the confirmation of exclusive hunting and gathering rights, the provision of employment opportunities in the various support services required to manage protected areas, and a share of any user fees that are collected.

B. Forest and Conservation Areas

10.10 The degree to which sustainable management of primary humid forests is possible within logging concessions is highly contentious. Although the evidence available at present may not be sufficient to make a definitive and categorical statement, there is increasing support among experts for entirely prohibiting logging in intact primary humid forests. Logging should be stopped in ecologically delicate and in environmentally important areas. There clearly should be no logging where it is not possible to log on a sustainable basis. In secondary forests (i.e., those consisting of regrowth where primary forests have been logged or otherwise significantly disturbed before), industrial plantations and tree farms, logging must be undertaken in accordance with sustainable management practices. These areas could, in many cases, be specifically designated and managed as permanent sources of timber, pulpwood and woodfuels -- provided the private owners (individuals or groups) agree. Logging companies unable to log in a sustainable manner should not be given concessions and permits, not even in secondary forest areas. This will require governmental regulation of logging, even if it is undertaken on private land.

10.11 Loggers will have to improve their performance and show themselves to be responsible in their logging activities. In order to induce this behavior, logging concession agreements providing for logging company responsibilities as well as rights will be necessary. Payment of taxes should be

¹ PRA techniques have been developed and refined in the 1980s, evolving from Rapid Rural Appraisal (RRA) techniques and agroecosystem analyses, to ensure maximum involvement by the local populations in local land use planning (resource inventory, problem diagnosis, resource use planning, action plan formulation, etc.). See, for instance, Chambers, 1991.

more the norm than is tax evasion. Management of secondary growth forests and industrial plantations would then become more important in the share of the business of logging companies than mining of primary forests. Even where governments choose to continue to allow logging in primary forests, management of secondary growth should be strongly encouraged by levying much lower taxes on trees taken from replanted areas and industrial plantations than on trees harvested from primary forests. If international prices for tropical wood rise as currently projected, the profitability of forest plantations will increase, making such an approach even more feasible.

10.12 Taxes on logging in those primary forests where logging is still permitted should be increased, through area-based taxes levied on concessions. Part of the tax should be collected and retained by local communities owning the forests. Concession agreements should be auctioned to the highest bidder. These measures would serve to return more of the benefit to the community and, in effect, impose a charge on the companies for the resource (the forest) exploited. Taxes should be high enough to reflect the economic and social value of the forest, including the environmental services it provides, and the cost of rehabilitation if the public sector or the local community undertakes that rehabilitation.

10.13 An environment this restrictive for logging must also be made consistent with management of the resource by local owners. It is increasingly recognized that maintenance of protected areas requires the direct involvement of the local and surrounding populations. It is unrealistic to expect communities to conserve forest and wildlife resources unless such conservation provides these communities with clear benefits. The exclusionary approach so often taken in protected areas in the past is neither workable nor sustainable nor equitable. Governments cannot financially afford and effectively provide the degree of enforcement needed. And the local populations, frequently among the poorest, are left to bear the costs of restricted access to resources, exposure to marauding wildlife, etc.

10.14 Governments will need to provide the essential policy and administrative framework: publishing standard concession agreements, establishing and collecting taxes and stumpage fees, and creating conservation areas, based on both land use plans and national forest policy parameters. Implementation would be the responsibility of the local communities, with the requisite technical assistance provided by government agencies and/or NGOs. As these communities acquire experience and management acumen, the need for such outside assistance will decline and government support should be commensurately withdrawn. As emphasized above, strong and lasting incentives (embodied in resource ownership, user rights, revenue sharing, and the like) would need to be provided to ensure appropriate local interest in such an approach to resource management.

10.15 Reflecting the recognition that effective resource conservation and management must involve strong local participation, the concept of "Integrated Conservation and Development" is being developed. It involves the following key aspects:

- (a) Local populations retain the rights to continued traditional utilization of resources inside state-owned protected areas to the extent that this is not detrimental to the ecosystem and are, of course, allowed to continue such activities on all land returned outright to them.
- (b) The local communities are allowed to generate income from protected areas through environmentally compatible activities such as tourism, hunting with traditional weapons, and gathering of non-timber forest products. All of these activities are directly dependent on the protected area. Local communities given exclusive rights to carry out these activities will have an incentive to conserve the forest or wilderness area.

- (c) **Buffer zones are established around core protected areas where the land and resource ownership is returned to the local communities and which will provide them with forest and agricultural products without overexploiting the protected areas.² Buffer zones also serve to keep potentially destructive wildlife away from villages, crops and domestic livestock.**
- (d) **Agriculture and social development activities can be provided outside protected areas to attract local populations away from these areas and as an incentive to avoid encroachment.**
- (e) **Commercial logging of protected areas would be entirely excluded. Logging would be allowed and carefully managed only in those areas identified for logging, but on a sustainable basis.**

10.16 Actual experience with implementing the "Integrated Conservation and Development" concept is still limited in Sub-Saharan Africa. A number of pilot projects have been initiated, but are at a very early stage. The most important element is agricultural intensification outside the forest areas. Only rapid increases in output per unit of land will induce a fast growing population to stay out of the forests. Without agricultural intensification the forests and wilderness areas of Sub-Saharan Africa stand little, if any, chance of survival in the longer run. The ultimate environmental collapse can be postponed by reducing the rate of population growth. The preferred option combines maximum agricultural intensification with sharply curtailing population growth and far more determined and effective management of environmental resources.

10.17 Experience to date with this approach to conservation indicates some of the key constraints to successful implementation:

- (a) **The overall policy and legal framework must be consistent with the conservation objective. For example, local communities need to be authorized to participate in the management and benefits of protected areas and the wildlife and other resources they contain. Resistance to this concept remains strong in most of Sub-Saharan Africa, as governments generally believe that benefits reaped from conservation areas should accrue to all citizens. Compromises will have to be made. For example, taxes can be levied on local community receipts from tourism, so that benefits may be shared more widely.**
- (b) **Social and institutional factors constrain implementation of community-based conservation strategies. The major problems are the general weakness of community organizations and the vastly unequal distribution of authority between the national and local levels. Most local communities in forest, range and wilderness areas are poorly organized and difficult to organize. Outside assistance is nearly always necessary.**
- (c) **Only in a small number of cases can protected areas be expected to generate sufficient revenues from non-exploitative uses (such as eco-tourism) to provide significant local income or to support significant rural development. In most cases, external financing**

² **Agro-forestry schemes utilizing useful indigenous trees have considerable potential for making buffer zones a viable proposition for the local populations. The Bururi Forest Project supported by USAID in Burundi, the Uganda Village Forest Project supported by CARE, and the Conservation of Oku Mountain Project in Cameroon are making successful use of buffer zone agro-forestry (Nair, 1990, p. 49).**

will need to be provided on a long-term basis. The national and international communities must contribute to the cost of maintaining the national and global heritage represented by the areas being protected.

- (d) Creation of an institutional and management capacity in government is a difficult process. This is rarely, if ever, the highest priority of governments; as a result, such agencies are usually neglected and financially strained. Again, international assistance is critical.
- (e) In the absence of agricultural intensification, conservation efforts are bound to fail.

10.18 Conservation of biodiversity depends directly upon preservation of natural habitats, particularly tropical moist forests which contain by far the greatest diversity of species outside of certain marine environments. Habitat destruction is the greatest cause of extinction of species overall. However, for certain species which are acutely endangered by commercial exploitation, additional protection is needed in the form of controls on harvesting and on international trade. Such controls can only be effective if the governments of both "producing" and "consuming" countries are committed to enforcing them.

10.19 While better and more effectively protected area systems are essential, the single most important factor to ensure the preservation of land-based natural ecosystems will be meeting the demand for food, wood and other agricultural and forest products on a sustainable basis. Soil and water resources must be protected by protecting important watersheds -- by maintaining natural forests and, where these are already degraded, by re-planting or allowing natural regeneration to take place. The critical question of meeting the needs for woodfuels and timber must be addressed from both the production and the demand side. While commercial logging of remaining primary moist forests should be greatly reduced (if not banned entirely), because the available evidence indicates that it cannot be sustainable, there must be a major increase in resources for the sustainable production of fuelwood and construction wood. This must come from farm forestry, as well as from industrial plantations and well-managed production forests located in areas where the original forest system has already been substantially altered by logging. At the same time, energy conservation must be promoted, both through economic policy measures (e.g., pricing) and through the development and extension of technical innovations.

The forest department in Zambia has created enough industrial forest plantations (45,000 ha by 1985) to satisfy anticipated domestic demand beyond the year 2000. The program was backed by a well-conceived and well-managed research program which established the viability of industrial forest plantations with fast-growing species, enjoyed consistently high standards of plantation maintenance and fire protection, and received the government's sustained political and financial commitment throughout its 15-year development period (Spears and Ayensu, 1985, p. 319).

The Role of Governments

10.20 There are important functions to be fulfilled by Government agencies. Governments should develop the institutional and human capacity required to prepare land use plans, manage protected areas and to monitor logging as well as the use of agricultural and pasture (and fisheries) resources. This is important to ensure that protected areas are in fact protected and that the areas made available for exploitation are used in a productive and sustainable manner. An example of management for sustainability is increasing the availability of wood products to match population growth -- ensuring, for example, that reforestation matches cutting. This could be done by convincing local communities and individual land owners to set aside sufficient land for wood production. The instruments to achieve this would chiefly be those of ensuring that price, tax and

other incentives make tree planting, harvesting and marketing profitable (and more profitable than other forms of land use on the land most suitable for tree production). This requires planning and management capacity in Government to help local populations manage natural resources. In parks and protected areas, governments will need the capacity to manage resources directly and effectively.

10.21 Government forest services can also help local owners reforest degraded forest land by providing planning assistance, seedlings and training. But the planting, maintenance and harvesting must be done by the local people themselves. Forest services need to concentrate on extension and research functions on private and community-owned land, rather than on direct management. NGOs can play important roles in assisting local people in managing natural resources, and where they are ready and willing to assume this role, they should be given wide room to do so. Governments should also intensify their efforts to provide effective and locally relevant environmental education through the school system and through mass media. Agricultural extension staff should similarly be utilized to spread awareness of environmental issues among rural populations.

A New Forest Policy in Côte d'Ivoire

In Côte d'Ivoire, about 12 million ha of tropical forest land have been lost since the turn of the century. To arrest this destruction, the Government has initiated an effort to implement a number of the recommendations set out here. The objectives of this program are to arrest destruction of tropical forests and restore forest cover on about 20 percent of the country. Wildlife and biodiversity would be conserved in national parks covering 1.9 million ha, of which 600,000 ha are tropical forests. Sustainable production of logs would be undertaken through better management of forest reserves for logging (all of which are secondary forests, previously logged), maintenance and expansion of hardwood plantations, and assistance to farmers induced to resettle outside the forests, some of whom will produce wood on their farms.

This process begins with detailed land use plans for existing "gazetted" forest areas belonging to the state. The plans designate land for protection, logging, farming and/or other uses. Park areas have already been delimited and are to be fully protected and managed. In those parts of the gazetted forests which have been previously logged over and are to remain production forests, concessionaires would receive long-term concessions for sustained logging in accordance with detailed forest resource management plans and under governmental supervision. Loggers who receive long-term concessions would be required to manage these for sustained logging under governmental supervision. Loggers unable or unwilling to participate would not be permitted to log. To generate the greatest amount of forestry value for the government, taxes on logs have been increased, and concessions will be auctioned to the highest qualified bidders. This is already eliminating the least efficient loggers. In effect, forests are no longer being treated as a virtually free good, but as an expensive and valuable resource to the community, requiring high payment by logging companies for exploitation. Intact primary forests are not to be logged at all.

Farmers are to receive incentives to move out of parts of parks and logging reserves. The key incentives will be land ownership outside these areas and reliable access to agricultural inputs. The agricultural extension service will provide technical advice. No support services will be provided to farmers remaining inside the forests, unwilling to move. There will, however, be no coercion to move; the incentives are expected to be sufficiently persuasive to induce voluntary exit from the park and logging areas. Traditional forest dwellers would be allowed to remain in the forests; so would farmers settled in areas already so heavily encroached upon that forests have essentially disappeared. Land tenure reform to eliminate open access to land is being initiated under a separate project. Government institutions in the forest sector will be strengthened to focus more on conservation and resource management, rather than on servicing the logging industry.

This new forestry policy fits into a broader national strategy to accelerate agricultural intensification and to improve land tenure security. Demand for smaller families would be stimulated through planned improvements in health care and in education, including female education. Many of the elements of the Nexus are therefore going to be addressed.

Major issues now are the need to find ways to promote local community involvement in conservation and to induce farmers to leave voluntarily those parts of the forests that are to be preserved as forests. Incentives for local communities around the forests will need to be provided in the form of certain use rights, a share in logging revenues, and employment opportunities in the forest and park service. In the medium term, incentives for conservation would be more powerful if farmers and traditional forest dwellers owned the forest. A consultation process has been initiated in forest-farmer commissions for each forest in which these issues are to be freely discussed with full participation of people living in these forests and the surrounding areas.

Financing

10.22 The benefits of improved conservation of tropical forests will accrue to the entire world, while the costs will have to be borne almost entirely by the countries in which the forests are located. This situation has stimulated efforts to reimburse the producing countries for losses incurred when forests are taken out of production and put into reserves. The first such efforts were "debt for nature" swaps. Although not many swaps have been organized in Sub-Saharan Africa, there is no doubt that there is considerable potential for them in many parts of the continent. The principle is that governments agree to set aside as a protected reserve large tracts of forest or wildlife area, usually administered with the help of an NGO, in return for the purchase of some amount of the country's discounted debt by the NGO, or organized by the NGO.

10.23 A recently launched initiative is now underway to provide about US\$1 billion for a Global Environmental Facility (GEF). These funds would be made available to countries as compensation for reducing activities that are remunerative but significantly compromise biodiversity (such as logging), contribute to carbon dioxide emissions (such as forest burning), or produce CFCs. Setting aside of tropical forest land as reserves and parks is a good candidate for funding under this Facility.

C. Dryland Areas and Pasture Land

10.24 Dryland areas will, like forest areas, require special protection. Actions in the agricultural, livestock, infrastructure, land tenure and population spheres along the lines set out in previous chapters will be necessary, but not sufficient. Because agricultural technology adapted to dryland areas is so marginal, land tenure reform so exceedingly difficult to implement, and carrying capacity so low, sustainable management of dryland areas will be very problematic.

10.25 Two recent reviews of key issues in Sahelian dryland management highlighted a number of essential concerns that should be observed in attempts to ensure sustainable management and development (Nekby, 1990; Shanmugaratnam *et al.*, 1991). These include the research and extension of appropriate crop and livestock technologies which are both soil conserving and more profitable for farmers and herdsmen, land tenure reform to eliminate open access, reduction of population growth through out-migration, and promotion of non-agricultural rural industries to reduce the pressure on land. One of these reviews (Nekby, 1990) also suggested a return to holistic and integrated planning and execution -- in effect, a return to the concept of integrated regional development based on land use plans that allocate land for pasture, cropping, reserves and parks, fuelwood production, forests and other uses. Land ownership would be allocated, including to traditional community or clan owners. Agricultural and livestock technology would be developed to suit each particular agro-climatic situation. The technologies would include considerable soil conservation measures. It is, at present, not possible to envisage an alternative approach in dryland areas.

10.26 Local initiative and management need to be mobilized in a manner similar to that described above for the forest areas. Group land titles should be provided. It is through the ownership of land and of natural resources that local participation can be mobilized. In better watered grazing lands, individual ownership of ranches will be possible, but this will not be generally feasible on dry lands due to the patchy availability of water and the need for seasonal livestock movement. But exclusion of others -- i.e., elimination of open-access conditions -- is essential. Hence the need for group titles to land. At the same time, local communities and individuals need to be taught to plan and manage resource use. Communities will require funding to do this (such as the micro-project funds which some donors have begun to establish). Technical assistance will have to be provided to communities to assist them in this planning.

D. Water

10.27 In large parts of Sub-Saharan Africa, water is the critical limiting resource, and conflicts over competing uses are becoming evident. In some areas, groundwater reserves are being drawn down for irrigation much faster than they can be replenished. Damming and diversion of rivers for irrigation or hydro-power development has often created serious problems downstream. These include the spread of water-borne and water-related diseases, coastal erosion, intrusion of saltwater into groundwater aquifers in coastal areas, destruction of woodlands and wetlands of critical importance as wildlife habitat, and destruction of downstream fisheries and coastal wetlands critical for marine life. Water pollution from domestic sources has become a major concern in many areas, both around coastal cities and in countless areas where lack of safe potable water is the most serious public health problem. In some regions, pollution from agrochemicals is emerging as a problem, as it already is in other parts of the world. Water must be recognized for the critical and limiting resource it is: it must be carefully allocated through the development of local and regional water use plans and protected against pollution.

E. National Environmental Action Plans (NEAPs)

10.28 The development of national environmental resource management strategies must be a national affair. The main vehicle used for this process is the National Environmental Assessment and Action Plan (NEAP). NEAPs are currently being prepared or implemented with World Bank support by more than 20 African countries. They should contain strategies for addressing all of the issues of the nexus. The NEAP concept is multi-sectoral in approach, and oriented to bottom-up participatory planning and implementation. It provides a framework for integrating environmental concerns with social and economic planning within a country. The objective is to identify priority areas and actions, develop institutional awareness and processes and mobilize popular participation through an intensive consultation process with NGOs and community representatives.

10.29 A successful national approach to environmental concerns involves several important steps:

- Establishing policies and legislation for resource conservation and environmental protection that are integrated into the macroeconomic framework and, if possible, assessing the costs of degradation.³
- Setting up the institutional framework, usually involving a ministerial or higher-level environmental policy body, developing mechanisms for coordination between agencies, building concern in these agencies, balancing private and public sector concerns, decentralizing environmental management, and assuring continuous contact with local people. The preparation of regional land use plans could be an important component. The basic framework needed to guide the implementation of land tenure reform, forest policy reform and other elements discussed above can also be included in NEAPs.
- Strengthening national capacity to carry out environmental assessments and establishing environmental information systems. This can be done to some extent by restructuring existing data and making them available to users. Pilot demand-driven information

³ These were, for example, estimated to be between 5 and 15 percent of annual GNP in Madagascar and more than 5 percent of GDP in Ghana.

systems should also be initiated to strengthen national capacity to monitor and manage environmental resources. Local and regional research capacity will be crucial to the development of plants and technologies which are truly adapted to local conditions.

- Developing human resources through formal and on-the-job training; introducing environmental concerns into educational curricula; and increasing public awareness through media coverage and general campaigns.

10.30 NEAPs are intended to be evolutionary – developing policies through field experience as well as national-level analysis. They should lead to the empowerment of the non-governmental sector, not just by providing funds for small-scale community activities through national environmental funds, but also by drawing large numbers of village and district representatives into consultative forums. A non-governmental advisory body was part of the institutional arrangements set up, for example, under the Lesotho NEAP.

10.31 Considerable external support has been provided for the NEAP process, from bilateral and multilateral agencies and NGOs (such as the World Wildlife Fund, the World Resources Institute, and the International Institute for Environment and Development). Donor expertise is made available to the countries undertaking NEAP preparation, and donor policies are coordinated in the process, with the NEAP forming the basis for coordination. Where NEAPs have led to the preparation of national environmental investment plans (as in Madagascar and Mauritius), donors have substantially oversubscribed the programs. An NEAP can therefore become the major preparatory instrument for addressing the issues discussed in this chapter.

Geographic Information Systems

Lack of operationally meaningful and reliable environmental data is a major problem. It tends to result in misconceptions about natural resource problems and the consequent risk that policy measures will be misdirected. Urgent needs include assessments of forest cover, soil erosion and soil capability, desertification risks, and the distribution of human and livestock populations. This is clearly an area in which donors can provide support and expertise and governments need to act. It is important to develop national capacity to gather and analyze information in-country: properly designed and operated Geographical Information Systems (GISs) can be extremely helpful in this regard. GISs make use of aerial photography, remote sensing and actual ground inspections and data collection. GISs will be particularly useful not only to monitor the progress of natural resource degradation and destruction, but – more importantly – to assess land capability for various uses and, thus, to provide the basis for sound land use planning.

XI. CONCLUSION

A. The Problem

11.1 The countries of Sub-Saharan Africa face three important challenges: (a) reducing the rate of population growth, (b) safeguarding their natural resource base, and (c) making agriculture, as quickly as possible, sufficiently productive to ensure rising standards of living for the rapidly increasing population without further endangering the resource base available for this purpose. Because these three challenges are closely interlocking, the ambitious indicative targets set out in Chapter VI in each of these areas are more likely to be achieved if the actions suggested in each specific area are successful.

11.2 Rapid population growth, environmental degradation, and slow agricultural growth observed in Sub-Saharan Africa are closely linked. The principal problem is that shifting cultivation and transhumant pastoralism, adapted to low population density situations, are environmentally damaging when practiced by rapidly increasing populations. When population densities increase and shifting around on the land becomes impossible, but farming practices do not change, soils degrade and forests are destroyed. Soil degradation and deforestation constrain agricultural growth. Lagging agricultural growth perpetuates rural poverty and food insecurity, which in turn impede the onset of the demographic transition to lower human fertility rates.

11.3 Past efforts have, on the whole, failed to reverse the direction of the downward spiral that is driven by the synergetic forces of this Nexus. The explanation, at least in part, appears to be that past efforts have been pursued too narrowly along traditional sectoral lines -- matching established institutional arrangements and traditional academic disciplines -- while crucial cross-sectoral linkages and synergies have been ignored. Environmental integrity and resource conservation are critical for sustainable long-term growth of agriculture, and of the economy. But this will be very difficult to achieve if present rates of population growth persist. Population growth is unlikely to decelerate unless there is more vigorous growth of agriculture, and of the economies dependent on agriculture. At the same time, agricultural growth based on traditional patterns of resource use and production technologies will be increasingly constrained by rapid population growth and the degradation of the environmental resource base.

11.4 A significant conclusion of this study is that far more emphasis needs to be placed on efforts designed to promote effective demand for sustainable and environmentally benign farming technologies, for family planning services, for resource conservation. Considerable emphasis has been placed in most past sectoral development efforts on the supply side (i.e., efforts to develop and deliver technology and services), while the need to generate demand has remained largely unrecognized -- or at least poorly served. The synergies inherent in the Nexus provide considerable potential for addressing the demand side of these important problems.

11.5 There is low demand for small families, as well as an inadequate supply of family planning services. Both are keeping total fertility rates high. Low demand for small families is due to cultural factors, high infant mortality, low education for girls, and limited family planning services. More contentious is the impact of economic incentives. High demand for child labor may be created by systems of shifting cultivation, severely constrained access by rural women to production inputs other than child labor, additional demand for child labor as part of a survival strategy in the face of poor food security and increasing degradation/depletion of soil and water resources. Demand for smaller families is manifesting itself, however, where the density of

population on cultivated land is high, infant mortality is low, food security is high, and female school enrollment rates are high. Countries with these characteristics are entering the demographic transition, and family planning programs are likely to be extremely effective there in responding to the strongly emerging demand for family planning services.

11.6 Forest degradation is stimulated by rapid population growth combined with shifting cultivation (people moving into forests to farm), poorly regulated logging, and "open access" land tenure. "Open access" occurs when there is no effective regulation of land use, either traditional or modern. This allows farmers and others to exploit the land, and the resources on it, in a non-sustainable manner. Fuelwood prices which are too low to cover replanting costs, are constraining fuelwood planting. Fuelwood prices are low because it can be mined, nearly freely, from open access areas. Trees can be cleared for farmland by migrant farmers in open access situations.

11.7 Women's time is increasingly constrained in rural areas, as fuelwood and water become scarce. Women walk further for water and fuelwood as a result. Women have difficulty maintaining food output with less time available, contributing to food security problems.

11.8 Technological innovation which could permit traditional farming and livestock practices to evolve in an environmentally sustainable manner, is not keeping up with the present rapid rate of population growth. The present gap is enormous.

11.9 Lack of demand by farmers for new agricultural technology is as important as lack of supply of appropriate technology, in explaining slow agricultural growth. Lack of demand is related to several factors:

- Open access land tenure situations are replacing traditional land tenure systems. In open access, land occupation and use is temporary and there is no incentive for the farmer to invest in farm intensification. Open access also reduces the incentive for farmers to conserve the land (since it is not theirs).
- There is often a lack of capital and financial resources with which farmers (especially women) can invest. This low income trap is operable in much of subsistence agriculture.
- Labor constraints on women often prevent them from adopting those intensive technologies which are labor intensive.
- In much of Sub-Saharan Africa poor agricultural and economic policies, combined with currently low world prices for many agricultural products, have reduced the profitability of farming and hence the incentive to intensify farming. They have often restricted farmers' ability to participate fully in land management, marketing or price setting.
- Appropriate improved agricultural technology for farmers is often locally unavailable and/or unknown; there can be no effective demand for what does not exist or is not known to exist.

B. Recommendations for Action

11.10 To correct the current disastrous trends noted above, a set of mutually reinforcing actions need to be undertaken by governments and donors. One of the most important will be to

promote demand for smaller families and FP services. This needs to be effected through determined action in several areas – notably expanding primary and secondary education for females, reducing infant mortality, and providing culturally sensitive FP advice and services. Field surveys to identify the determinants of fertility and attitudes to family planning will be essential. Population programs are being prepared in about half of the countries of SSA. Political commitment will be necessary to implement them. Priority in establishing FP programs that emphasize increased supply should be given to countries where demand for fewer children is emerging – as a consequence of increasing population density on cultivated land, improving female education, declining infant mortality rates, improved food security and better conservation of environmental resources. Where these factors are not satisfactory, demand for children will remain strong and will blunt the effectiveness of programs oriented towards increasing the supply and accessibility of FP services.

11.11 Where AIDS is a serious concern, even in the absence of the elements that appear to spur the onset of the demographic transition, high priority must be placed on providing appropriate information and education regarding the prevention of sexually transmitted diseases as well as condoms through all available channels, such as schools, health facilities, traditional health providers, FP programs, pharmacies, NGOs, etc.

11.12 Strong efforts are also needed to create farmer demand for "environmentally sustainable" agricultural technology. Means to accomplish this include expansion of appropriate research and extension to farmers, the elimination of open-access land tenure systems, and agricultural policy which makes agricultural intensification profitable (and reduces the relative profitability of shifting cultivation). The priority development of rural roads and markets in areas designated for agricultural development will be important in this regard. Agricultural research establishments must be developed to supply the appropriate technology. The recent elaboration of Frameworks for Action under the auspices of the Special Program for African Agricultural Research (SPAAR) merits strong support, as do related efforts to improve other agricultural support services such as extension. Funding is not so much the problem as is organization and management.

11.13 Agricultural services and education must serve women, to stimulate reduced demand for children and improve women's farming practices. Successful introduction of agro-forestry and fuelwood production on farms would significantly reduce women's work burden in fuelwood gathering. Introduction of appropriate transport improvements and stoves that save both fuel and time would also help. Improving rural water supply will save women's time. It will also reduce infant mortality, thus reducing the demand for more children. Success in these areas will free more of women's time for family management, agricultural production and other economic activities.

11.14 Measures necessary to create a market for fuelwood should be pursued. Fuelwood prices should reflect the scarcity value and replanting costs of trees. Higher prices would stimulate farmers and entrepreneurs to plant trees. This will require land tenure reform to eliminate open access to free fuelwood by farmers and entrepreneurs. It will also require extension advice to farmers on agro-forestry and fuelwood plantations. Eliminating price and taxation disincentives to the marketing of kerosene and other substitute fuels would stimulate the substitution of such fuels for woodfuels over time, particularly in urban areas.

11.15 The rate of degradation and destruction of forests and wildlands can be reduced by determined pursuit of agricultural intensification. This needs to be promoted through the measures indicated above, the elimination of open-access land tenure situations, keeping infrastructure out of environmentally sensitive areas, and more effective regulation and taxation of logging.

11.16 Environmental action plans should be prepared which focus on agricultural and demographic causes of environmental degradation in rural areas. A key instrument to be used in preparing solutions will be land use plans. These define the use to which various types of land are to be put (forest, protected areas, agriculture, settlements, infrastructure, etc.), given various demands.

11.17 Infrastructure development in rural areas, particularly roads and water supply, is important for agricultural development and to focus population settlement outside of environmentally sensitive areas. Keeping infrastructure out of environmentally sensitive areas is an important tool for conserving those areas. Infrastructure investment in rural areas and in secondary towns merits considerably higher priority than it has received in most countries in the past. Infrastructure development should be in response to demand. This is likely to result in smaller-scale investments rather than massive engineering efforts which have to date characterized much government and aid agency spending. Demand responsiveness will be stimulated by more community and local control over infrastructure design and siting, by the use of local private contractors, and by funding facilities constructed and maintained by the user communities themselves.

11.18 Urban areas represent outlets for population increases, markets for agricultural products and fuelwood, sources of manufactured inputs and consumer goods for farmers, and centers for the provision of educational, health and other services. Urban development needs to be one component of land use plans. Further, urban policy should be developed in part as a function of likely growth of the urban population, linkages between urban and rural product and labor markets, communications needs in rural areas and environmental constraints. Generally, policies which promote development of secondary cities and rural towns, rather than of a few mega-cities, will be far more conducive to efficient, equitable and sustainable rural development. This requires spatially well distributed public investment which is not biased in favor of mega-cities, sound and substantial investment in infrastructure throughout each country (rather than concentration in mega-cities). It further requires functioning markets and market-based pricing for petroleum and other energy sources, avoidance of transport monopolies to increase the likelihood that the entire country is adequately served by private transport providers, promotion (through industrial extension, investment codes, credit facilities) of small and medium enterprises located in secondary cities and rural towns, and decentralization of political decision making outside capital areas to facilitate greater responsiveness to demand. These are not only crucial elements of sound urbanization policy, but are important for rural development because well functioning secondary towns and cities are more likely to provide services and markets for rural areas than are distant mega-cities which tend to be heavily oriented to overseas suppliers.

11.19 Local communities need to be empowered to participate in all of the above. Without participation, people will not demand smaller families, sustainable agricultural technologies, road maintenance or forest conservation. Participation is more likely to result in development initiatives which respond to felt needs rather than to short-term political imperatives and expediencies. People should become managers of actions conceived in partnership with Governments.

11.20 Multi-sectoral and cross-sectoral thinking is needed to resolve agricultural, population, settlement and environmental problems -- because of the important linkages and synergy between them. Environmental protection will be very difficult to achieve if present rates of population growth continue. Population growth is unlikely to decelerate unless agriculture, and the economies dependent on agriculture, grow more rapidly. Agriculture will be increasingly constrained by rapid population growth. Settlement and urban development policies are important factors influencing population growth and movement, agriculture and environmental resource use. In this regard, the analysis suggests that spatial planning would be desirable, and that action plans covering the various sectors

should be integrated at the regional level. In particular, land use plans should be developed with a spatial and regional focus. Such plans should identify conservation areas, logging areas, farming areas, and locations for settlements and infrastructure development. Appropriate farming technologies vary from one micro-agro-climatic zone to the next. Technology is location-specific. Land tenure problems, fuelwood problems and even cultural patterns defining human fertility will vary from place to place in the same country. There is therefore merit to having regional action plans for conservation, agricultural technology, land tenure reform, fuelwood, forestry, etc. Regional plans need to be structured around networks of markets and towns and include the transport and communications infrastructure that links them.

11.21 Because such plans will be complex and difficult to implement, they should in most cases not be implemented through integrated multi-component projects. Conservation and land use plans specified by location would be one cluster of projects. Appropriate agricultural technology for each micro-region could be developed and extended through national research and extension programs, with regional implementing divisions. Regionally specific land tenure reform could be implemented under national land tenure reform programs. Population actions adapted to particular communities would be implemented through national population and family planning programs. Urban and infrastructure development will constitute separate projects. But there needs to be a sensible fit between these separate projects and investments, given the synergies and complementarities between them.

11.22 Several other important recommendations emerge from this study concerning analytical work that should precede the formulation of action plans and, particularly, of developmental interventions -- be they investment projects or institutional and policy reforms.

- Far greater attention needs to be paid to the social organization of production and consumption, of decision-making and resource allocation, of access to resources and services. These systems and structures can be very complex and often differ substantially among communities (and certainly among countries) throughout Sub-Saharan Africa.
- This implies the need to use relevant "units of analysis". The casual and often indiscriminate use, for example, of the "household", the "family" and the "family farm" may not be appropriate if these terms are simply assumed to convey concepts of social and economic arrangements familiar to 20th-century industrialized economies. Most African societies are characterized by complex systems of resource-allocation and -pooling arrangements for both production and consumption purposes, based on lineage, kinship, gender and age-groups -- often with multiple overlaps. It is imperative to be cognizant of, and sensitive to, these and to analyze the impact of development interventions on individuals in this context.
- Gender issues are critical, especially in terms of gender-specific divisions of responsibilities, tasks, and budgets, as well as in terms of access to resources, information and markets. Interventions and incentives do not necessarily work in the same direction or with the same intensity for men and women.
- More input is needed from sociologists and anthropologists to understand socio-economic systems and relationships. Social scientists should collaborate closely with agricultural scientists and economists in researching farming systems, cultures and socio-economic institutions into which new varieties and technologies are to be introduced.

Agriculturalists and economists in turn should receive special training to raise awareness of these issues. Local expertise needs to be much more drawn upon to improve our understanding of how things operate, why they operate this way, and what may work under these conditions.

- **Extremely important is the need to take into account the risk perception of the local people -- their absolute requirement for ensuring survival in the short term even under worst-case scenarios.**

C. Status of Implementation

11.23 The above recommendations are broad and need adaption to each country's special circumstances. In some countries, these ideas are already being pursued:

- (a) **Many countries in Sub-Saharan Africa are pursuing macro-economic and agricultural policy reform programs designed in part to improve the profitability of agriculture; this will stimulate the needed agricultural intensification. On the other hand, some countries do not yet have policies which would make agriculture profitable. Also, many donor countries maintain a combination of import barriers and agricultural subsidies to assist their own farmers, and this harms African producers of these commodities. These policies need to be changed.**
- (b) **An increasing number of countries in Sub-Saharan Africa are now developing environmental action plans. For these countries, implementation is the watchword. In the others, the process should be launched. Donor support should be intensified.**
- (c) **Agricultural research and extension systems in a number of countries are slowly shifting to a greater focus on "sustainable" agricultural technology and responsiveness to varying farmer demand. Collaborating with SPAAR, countries in the Sahel and SADCC regions are planning the improvement of their agricultural research systems. Other countries should follow suit, and donors should collaborate in implementing SPAAR's "Frameworks for Action".**
- (d) **At least four Sub-Saharan African countries (Botswana, Kenya, Mauritius and Zimbabwe) have, with considerable effort, succeeded in bringing down fertility rates. Much more needs to be done here in all SSA countries, but these four provide relatively successful models. Several others countries are now developing promising population and family planning programs. Genuine and sustained political commitment will be essential. Donor support should be channelled through the ongoing African Population Action Plans.**
- (e) **Improved health programs, including health education and the distribution of condoms, to address the AIDS problem are starting up in several countries.**
- (f) **The empowerment of local communities to manage development in each of the above areas is now beginning to be accepted in some countries; it requires much more effort.**
- (g) **Slow land tenure reform, inappropriate fuelwood pricing, and feeble rural infrastructure programs are major weak points everywhere.**

Kenya: The Nexus Synergies at Work

In Kenya, population density on cultivated land is high. Education is relatively good, and females participate. Infant mortality has declined due to relatively good health care, food security and women's education. Agricultural policy has been quite good, smallholder or commercial farming is profitable, and private sector participation in all aspects of agricultural production, marketing and processing is high. Land tenure security is assured (although there have been problems with land grabbing by influential elites as well as with the land rights of livestock herders and of women). Women are receiving attention from the agricultural extension service. Family planning programs are in place. Popular sensitivity to the costs of environmental degradation is high, and there has been successful environmental conservation action in the form of a national soil conservation program, the maintenance of sizeable national parks, and the widespread tree planting under the Greenbelt Movement promoted by a national NGO working almost entirely with women. Urban bias in economic policy is less pronounced than elsewhere in Sub-Saharan Africa, and the development of secondary towns and cities characterizes Kenya's urbanization policy. Relatively good infrastructure, including a country-wide network of roads, has been developed.

The combination of these (and other) factors has had a number of desirable results. Agricultural growth has been averaging between 3 and 5 percent per annum. Tree farming and other agro-forestry activities have increased, and the area under trees may now in fact be expanding. There is at least marginally effective protection of national parks and of wildlife. Farmers participate in marketing decisions, with farmer-managed cooperatives playing a significant role. Kenya's urban markets are stocked with Kenyan farm products, assembled in rural markets and secondary towns and brought to market largely by private traders. And the TFR has begun to decline measurably in recent years.

11.24 Major areas of deficiency in many countries of Sub-Saharan Africa remain rural health care and education (and particularly female education), rural infrastructure, promoting greater participation of local communities in development efforts, forest and conservation policy, land tenure reform, sound urbanization policy, and effective family planning programs.

11.25 Several SSA countries are pursuing many of the policies suggested here. By bringing much of this together, they are obtaining positive synergies between agricultural growth, environmental protection and reduction in human fertility rates. Kenya, Zimbabwe, Botswana and Mauritius are examples. They strongly suggest that the type of measures recommended here are likely to be effective. Others, such as Ghana and Tanzania, are moving in the right direction.

D. Conclusion and Issues

1.26 The new instrument needed for governments and donors to address these issues is first of all analytical. The issues presented here must be analyzed simultaneously, and action programs must be developed which address the linkages and synergies among them. A convenient and effective tool for this analysis may be the national environmental action plans and, within these plans, location-specific environmental action and resource use plans. An environmental action plan should be developed for each country. It should include an analysis of the factors discussed here and incorporate an action plan for governments, donors and communities to address these issues. In most cases, the action plan will consist of changes to agricultural research, extension and investment policy; increased focus on creating demand for family planning services and increased resources for population policy; greater emphasis on fuelwood and industrial forestry plantations and private tree farming; greater sensitivity to the environmental impact of all investments; more investment in natural resource conservation and protection; and land tenure reform. The role of women must be addressed far better in the areas of agricultural development and education.

1.27 Important tools for such planning will be integrated plans for regions showing allocation of land for various purposes, infrastructure development, land tenure reform and land ownership, fuelwood demand and supply, appropriate agricultural technology, likely migration, and likely

development of towns and cities. Most important will be the vastly greater community management of the execution of these plans. Communities and individuals must be given ownership of natural resources as an incentive for them to manage and conserve these resources. Better planning, particularly spatial planning, community and individual ownership of assets, and community management of implementation are the main directions in which donors and governments must move in the future.

1.28 Another key conclusion of this study is that agricultural sector analysis and planning do not make sense if they are undertaken in isolation from population planning and environment policy. Similarly, analysis of population or environmental issues in isolation makes no sense. There is much to be gained by multi-sector analysis. Action, however, should be defined within single sectors to facilitate efficient implementation.

1.29 There are numerous issues which require more focused and detailed research. Among them are the following:

- (a) There is a need for further research to ascertain the relative importance of the various factors that influence human fertility decisions and trends. Gender-specific analysis is particularly essential in this area.
- (b) The expected impact of AIDS on population growth has been incorporated in the most recent population projections used here. However, given the difficulty of predicting its impact, the possible margin of error is considerable. More research is needed. Should AIDS turn out to have even more devastating impact on demographics than currently anticipated, improved health care, FP services and education focused on preventing sexually transmitted diseases and increasing the use of condoms could become the single most important intervention to be undertaken in Sub-Saharan Africa.
- (c) More analysis is needed concerning the productivity potential of the environmentally benign and "sustainable" agricultural technologies identified. The environmental effects of "green revolution" technologies also need careful study.
- (d) Work is needed to determine and test the degree to which communities and community groups will be conservation-minded if and when natural resource management is turned over to them by governments.
- (e) Urbanization and the urban-rural link are important determinants of key aspects of the agriculture-population-environment Nexus. More research is required in this direction.
- (f) There is some argument with the contention of this study that, although multi-sector planning is necessary, multi-sectoral projects to implement these plans may be undesirable. Specifically, some writers suggest that regional development plans could in many cases be implemented in an integrated fashion. Although this makes conceptual sense, the disappointing past experience with integrated rural development projects suggests that such programs are too complex to be managed as integrated wholes. How best to implement integrated location-specific plans through manageable components remains an issue to be explored.
- (g) The equity impact of these recommendations needs further scrutiny. Reducing open access to land, expanding the areas under protection, raising the price of woodfuels will

have negative effects on some of the poor. However, improved agricultural technology successful family planning, better access to rural health and education facilities and services, improved rural infrastructure, sound urban development will have positive impact on the poor.

11.30 The follow-up to this study has been launched. It includes the preparation of country-specific population, agriculture and environment nexus studies in Côte d'Ivoire, Ethiopia, Malawi, Nigeria, Rwanda and the Sahelian countries as a group. These studies will help firm up the analytical framework and will be instrumental in adapting the analysis to the situation of specific countries. Follow-up also includes widespread incorporation of Nexus issues in both environmental action plans and investment projects. Concurrent monitoring is underway regarding the progress of preparation and implementation of national environmental action plans and of national population programs. The mechanism for the former is the "Club of Dublin", consisting of representatives of African governments and donor agencies. The institutional mechanism for deepening the population agenda for Sub-Saharan Africa and for monitoring its progress is the African Population Advisory Committee, with similar membership. It is hoped that a similar African Agricultural Advisory Committee, managed by prominent Africans, will also be established.

Annex: STATISTICAL TESTS OF KEY HYPOTHESES

A. Methodology

1. Statistical analysis was undertaken to test several of the hypotheses discussed in this study. The statistical tests were highly imperfect because of lack of data and/or the poor quality of some of the available data. Reliable data on environmental resources and their degradation and/or destruction are particularly difficult to obtain, but agricultural statistics are also often of limited reliability. Demographic data are continually improving as a result of advances in sampling techniques and increasing support for information gathering from various sources. Nevertheless, considerable effort was devoted to data collection, represented in the statistical tables of this report. For the statistical analysis, data covering 38 countries of Sub-Saharan Africa were used. These are reproduced at the end of this annex. The methodology is cross-sectional, looking at statistical relationships among variables for which country observations are available.¹

2. The hypotheses were tested by assuming that statistical associations in the variations in variables across countries will similarly reflect associations between changes in these variables over time within countries. If, for example, cereal yields are significantly higher in countries with less cultivated area per capita, the assumption implied here is that a decline in cultivated area per capita in a given country will provide a stimulus for farmers in that country to intensify their farming practices and thereby increase crop yields. This assumption is not necessarily true. Cross-country data at a given point in time are obviously not the same as data depicting developments in the same setting over a long period of time. Moreover, a good explanatory model is not necessarily a good predictive model. For these reasons, and others described below, the statistical analyses undertaken here cannot prove or verify the hypotheses posed in this study. The statistical analysis is useful for specifying more clearly the hypotheses of this study and for testing whether the available data, using cross-sectional regression analysis, are consistent or inconsistent with these hypotheses.

3. Because of the above problem, additional data are now being collected to re-test the hypotheses and determine the robustness of the results obtained.

B. Variations in Crop Yields Among Countries

4. Many of the relationships hypothesized and discussed in this study cannot be investigated statistically using aggregated data. However, limited testing may establish the plausibility of several of the hypotheses:

- Crop yields should be higher where population is growing most rapidly relative to cultivated land. People begin to intensify agriculture as cultivable area per person declines. Hence, statistical analysis should show an inverse relationship between area cultivated per person and crop yields (all other things equal). However, the hypothesis of the study suggests that the rate of growth in yields stimulated by declining availability of cultivable land per person will be significantly lower than the rate of population growth.

¹ The role of women in agriculture and the effect of the land tenure situation could not be quantified and therefore were not tested in their impact on yields.

- Efforts to stimulate intensification (through the promotion of fertilizer use, for example) will significantly accelerate the increase in crop yields beyond the growth rate stimulated by rising population density alone. This should be observed as higher yields in countries with higher intensities of fertilizer use (all other things equal).
- Primary school education, of men and women, should facilitate farmer adoption of intensive farming techniques and therefore be associated with higher crop yields.
- *Ceteris paribus*, countries with more rapid degradation of their natural resource endowment, as reflected in higher rates of deforestation, should have lower crop yields.
- Finally, countries with a policy environment more accommodating for profitable market-oriented farming should have higher crop yields than countries with less conducive policies.

5. A statistical relationship was tested with cereal yields (average over 1984-86) as the dependent variable, using as independent variables: average cultivated area per person (average 1965-1987), fertilizer use per ha in 1987/88 (fertilizer use remained fairly stable in the 1980s), the percentage of the school-age population in primary school (average 1965-1987), the rate of deforestation in the 1980s, and the general "appropriateness" of agricultural policy during the period 1980 to 1987. Except for the rate of deforestation and the dummy variable for policy "appropriateness", the values for each variable were converted to their natural logarithm and a regression equation was fit to these data; the coefficients reported below therefore represent elasticities. Policy appropriateness is represented by a dummy variable having the value 1 for countries where policy is judged to have been conducive to profitable agriculture, and 0 where it is judged to have been inappropriate. Of the 38 countries considered, 24 were judged to have pursued inappropriate policies, 14 appropriate; these judgements are highly subjective.

6. The equation is as follows, where the dependent variable is average cereal yields in 1984/86 (natural logarithm):

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u> ²
Constant	5.45	10.1	1%
Cultivated area (ha) per person (a)	-0.33 (b)	2.5	2%
Fertilizer use per ha (a)	0.10 (b)	1.7	10%
Primary school enrollment rate (a)	0.17 (b)	1.2	24%
Deforestation rate	-0.05	0.9	39%
Agricultural policy dummy	0.30	1.9	7%

Adjusted R squared = 0.45
F Statistic = 7.0

- (a) Converted to natural logarithm.
- (b) Represents elasticity.

² The 2-tail test indicates the probability of the coefficient actually being zero. In the present example, there is, thus, a 2 percent probability of there being no significant relationship between cultivated area per person and cereal yields.

7. The equation explains about 45 percent of the differences in cereal yields among the 38 countries. The unexplained portion of 55 percent is due to rainfall differences between countries, differences in land tenure problems (as hypothesized in the text), differences in soil degradation and soil fertility, and data problems. Each of the variables, except deforestation and primary school enrollment, is statistically significant at the 90 percent level or better in explaining variations in cereal yields across countries (i.e., a 10 percent probability or less that the coefficient is actually zero).

8. Consistent with the Boserup hypothesis, and with the hypotheses advanced in this study, the lower the cultivated area per person, the higher are cereal yields, all other things being equal. The statistical relationship is highly significant. This suggests that as more people squeeze onto cultivated land, the pressure mounts for them to innovate and intensify production; it is true even when the use of fertilizer and other modern inputs, the policy environment and primary school enrollment rates are held constant. This reflects farmers' ability to respond to rising population density with simple innovations.

9. But, also consistent with the hypotheses, the coefficient is less than 1. This suggests that a 3.1 percent annual decline in cultivated area per person (due to population growth at this rate) will only stimulate people to intensify farming at a rate of about 1 percent per year -- i.e., much slower than the rate of population growth itself. Without additional effort and support to promote more rapid intensification of farming, people -- responding to population pressure alone -- will be unable, or unwilling, to raise crop yields fast enough. Historically, this is indeed what has happened. Crop land expanded at a rate of somewhat less than 1 percent per annum, and yields increased on average by slightly more than 1 percent per annum, giving an agricultural output growth of slightly less than 2 percent per year for Sub-Saharan Africa as a whole for the 1965-1990 period.

10. A increase of 1 percent in fertilizer use is associated with a 0.1 percent increase in cereal yields. The coefficient is significant statistically. Since fertilizer use is extremely low in Sub-Saharan Africa (averaging 85 grams per ha in 1987/88, compared to China, for example, where it is 2,360 g/ha), there is vast scope for increasing its use. This is also true for other modern tools and inputs (such as seeds of higher-yielding varieties), with which fertilizer use is highly correlated. Fertilizer use can therefore be considered a proxy for adoption of "modern" farming technology, and the coefficient linking fertilizer use to cereal yields picks up the effect of the use of other modern inputs as well. Growth rates of fertilizer use (and other modern inputs) of 10-15 percent per year during the next decade are feasible. This would stimulate growth of cereal yields, according to this equation, by between 1.0 and 1.5 percent per year.

11. A 1 percent increase in the proportion of primary school-age children enrolled in school is associated with an 0.17 percent increase in cereal yields, although the statistical significance is below the normal 90 percent threshold level. The results are sufficiently interesting to suggest further testing of the hypothesis that a more literate and knowledgeable people make better farmers. A better educated population as a whole may have a positive impact on farm productivity. This makes sense, since in most African countries the majority of the adult population is either working in agriculture, in farm input supply, agricultural marketing and processing, or in agricultural support services.

12. The dummy variable representing the adequacy of agricultural policy is statistically significant in explaining cereal yield variation among countries. A better policy environment is associated with higher yields, all other things being equal. The categorization of countries into those with acceptable and unacceptable policies during 1980-1987 (to coincide with cereal yields in 1984-1986) is consistent with the categorization by the World Bank; it is, however, highly subjective.

13. Consistent with the hypothesis, countries experiencing the most rapid deforestation have lower cereal yields, all other things equal, but the statistical relationship is not significant. The rate of deforestation is an instrument variable intended to reflect the rate of natural resource degradation (soil, water, and forests) on land not yet directly within the farming cycle. The low degree of statistical significance of the association between this indicator and cereal yields may be due to the fact that deforestation itself is related to population density, population growth, fertilizer use, education levels, and agricultural policy, as indicated below. The impact of deforestation on cereal yields is then picked up directly by these other variables. Additional data is now being collected to further test this relationship.

Variations in Yields of Major Individual Crops

14. The aggregation of different cereals into a single category obviously affects the quality of the equation in para. 6 above. Separate tests were therefore undertaken for maize, rice and sorghum, as well as for a major tuber crop, cassava, to determine the robustness of the results. These crop-specific tests face another problem: the lack of data on fertilizer use by crop. As the crop categories become less aggregated, so should the independent variables, but this is precluded by the lack of data.

15. The results of the statistical tests using the same independent variables as for cereals, but with yields of the four different crops as dependent variables are set out below.

16. Maize. The results for maize (natural logarithm) are consistent with those for cereals as a group, except that the policy dummy and primary school enrollment show no significant association, nor does the rate of deforestation. Maize yields are closely related to cultivated hectare per person and fertilizer use.

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	2.05	3.4	1%
Cultivated ha per person (a)	-0.27 (b)	1.8	8%
Fertilizer use per ha (a)	0.13 (b)	2.0	10%
Primary school enrollment rate (a)	0.09 (b)	0.6	55%
Deforestation rate	-0.07	1.2	25%
Agricultural policy dummy	0.10	0.5	61%

Adjusted R squared = 0.24

F Statistic = 3.3

(a) Converted to natural logarithm.

(b) Represents elasticity.

17. Sorghum. The results for sorghum (natural logarithm) are also consistent with the general findings for cereals, except that fertilizer use is negatively associated with sorghum yields and, as in the case of maize, that primary school enrollment shows no relationship. The inverse relationship between aggregate fertilizer use intensity and sorghum is curious and beckons further investigation. There are reports in the agricultural literature of such results in dry areas. Sorghum yields appear to be most closely determined by agricultural policy, deforestation (sensitivity to environmental situation) and cultivated area per person.

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	2.24	3.7	1%
Cultivated ha per person (a)	-0.23 (b)	1.6	12%
Fertilizer use per ha (a)	-0.11 (b)	1.8	9%
Primary school enrollment rate (a)	0.01 (b)	0.08	94%
Deforestation rate	-0.10	1.7	10%
Agricultural policy dummy	0.36	2.1	5%

Adjusted R squared = 0.11

F Statistic = 1.8

(a) Converted to natural logarithm.

(b) Represents elasticity.

18. **Rice.** The statistical relationship between rice yields (natural logarithm) and the set of independent variables show no significant statistical relationship. Unlike for maize and sorghum, the rate of deforestation, cultivated area per person, and the policy dummy have no association with rice yields. This is explainable by the more limited area, usually irrigated, on which rice is cultivated, and, therefore the lesser susceptibility to the environmental problems brought on by deforestation or land scarcity. The lack of association with fertilizer use is surprising.

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	3.21	3.5	1%
Cultivated ha per person (a)	-0.17 (b)	0.8	34%
Fertilizer use per ha (a)	0.11 (b)	1.2	26%
Primary school enrollment rate (a)	-0.25 (b)	1.1	27%
Deforestation rate	-0.05	0.5	60%
Policy dummy	0.40	1.5	15%

Adjusted R squared = 0.11

F Statistic = 1.8

(a) Converted to natural logarithm.

(b) Represents elasticity.

19. **Cassava.** Variation in cassava yields is very strongly associated with cultivated hectares per person, in the manner suggested in the text, as well as with inertia. Fertilizer use, primary education, and the deforestation rate have no impact. The policy dummy has an inverse relationship with cassava yields, unlike the relationship with cereals, but the relationship has very weak statistical significance. There may however be some tendency to move out of cassava as agricultural policy improves, and commercial crops such as cereals become more profitable to produce.

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	3.47	5.1	1%
Cultivated ha per person (a)	-0.70 (b)	4.2	1%
Fertilizer use per ha (a)	0.00 (b)	0.1	96%
Primary school enrollment rate (a)	0.00 (b)	0.0	99%
Deforestation rate	0.05	0.6	55%
Policy dummy	-0.29	1.3	20%

Adjusted R squared = 0.32

F Statistic = 3.9

(a) Converted to natural logarithm.

(b) Represents elasticity.

20. Overall, the test results for each crop were consistent with the results for cereals as a whole. They suggest: (a) the importance of inertia (the constant term) in explaining the level of crop yields; (b) the strength of the Boserup hypothesis (more cultivated area per person is associated with lower crop yields except for irrigated rice where there is no relationship); (c) the importance of the use of fertilizer (and probably other modern farm inputs) in raising yields of commercial and fertilizer-responsive crops such as maize, but not for some traditional crops (sorghum and cassava); (d) the negative impact of deforestation on the more sensitive crops such as sorghum, but less impact on the hardy cassava or on irrigated rice; (e) the importance of good agricultural policy for cereal crops (rice and sorghum; but, oddly, not for maize), but not for the subsistence crop cassava. There is a lack of association between primary education and any of the yields of the individual crops. The statistical relationships are not strong, and further testing with new data is underway.

21. This analysis suggests the plausibility (although not the likelihood) of achieving 4 percent annual average agricultural growth in Sub-Saharan Africa. Increased labor input per hectare, facilitated by population growth, would generate a 1 percent increase in annual output growth. A 15 percent annual increase in the use of fertilizer (and of other modern inputs) would generate an estimated 1.5 percent annual increase in yields. Allowing also for further expansion of cropped area at a rate of 0.5 percent per year (compared to the present rate of 0.7 percent per annum), this gives a total output growth rate of 3.5 percent per annum. The additional stimulus required to reach the postulated aggregate target of 4 percent growth per annum would need to come from more countries adopting more appropriate agricultural policy and from primary school enrollment increasing at 2 percent per year. In the longer run, however, as population growth slows, the scope for further policy improvement and expansion of cropped area narrows, sustaining 4 percent annual growth will become more difficult. It will depend increasingly on greater use of modern inputs and equipment, genetic improvements in crops and livestock, and improvements in general levels of education. This underscores the importance of improved agricultural research and extension and of general education.

C. Variations in the Rate of Deforestation Among Countries

22. The analysis in Chapter IV suggests that deforestation is related positively to population pressure on cultivated area (the lower the cultivated area per person, the higher the rate of deforestation), to the rate of population growth (the higher the rate of population growth, the higher the rate of deforestation due to land clearing and fuelwood gathering), and with policies favorable to agriculture (the more profitable agriculture and logging, the more rapid the clearing of forests). It is negatively related with the use of modern farm inputs such as fertilizer (the greater the use of

modern farm inputs, the lower the need to clear more forest land for farming). Open access land tenure situations were also hypothesized to stimulate deforestation, but this cannot be measured.

23. To test this hypothesis, regression analysis was undertaken with the rate of deforestation 1980-1988 as the dependent variable. Independent variables include the number of hectares cultivated per person (average 1965-1987), fertilizer use per hectare (1987/88), the population growth rate (1965-1990), and the agricultural policy dummy variable. The resulting equation is as follows:

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	-0.54	0.41	69%
Cultivated ha per person (a)	-0.60 (b)	1.50	15%
Fertilizer use per ha (a)	-0.19 (b)	1.17	25%
Population growth rate	0.56	1.40	17%
Agricultural policy dummy	0.76	1.65	11%

Adjusted R squared = 0.09
F statistic = 1.92

- (a) Converted to natural logarithm.
- (b) Represents elasticity.

24. None of the variables is statistically significant at the 90 percent level or above, in its association with deforestation, although the agricultural policy dummy, cultivated hectares per person, and population growth are close enough to suggest further testing. All of the coefficients have signs consistent with the hypothesis. The overall equation does not explain well the variation among countries in the rate of deforestation. Evidently, a number of other unquantifiable factors are at play, such as the land tenure situation, climate, and logging policies. No doubt, the poverty of the data also reduces the tightness of the fit.

25. Despite the poor overall fit of the equation, it suggests the possibility that countries with more cultivated area per person have lower rates of deforestation, all other things being equal. Countries with higher intensity of fertilizer use have somewhat lower rates of deforestation. Countries with more rapid population growth generally have higher rates of deforestation. Countries with policies that are conducive to agricultural development have higher rates of deforestation -- implying a trade-off between agricultural growth and deforestation.

26. If further testing with better data confirms the statistical validity of these relationships, it will suggest that slowing population growth and intensifying agriculture would slow the rate of deforestation. Although poor agricultural policy (which usually also entails poor policy for the timber industry) would reduce deforestation, this is not a useful instrument to apply, because the objective of accelerating agricultural growth will take precedence over that of reducing deforestation in every country. Hence the importance of environmental action plans and land use planning, which develop mitigating actions to reduce the negative environmental impact of agricultural development and which should serve to focus agricultural growth into environmentally less destructive channels (see Chapters VIII and IX).

D. Variations in the Loss of Wilderness Areas Among Countries

27. Table 20 shows the percentage of wilderness area lost since about 1900 in each African country. As in the case of deforestation, it is hypothesized that the degree of wilderness loss is associated with declining levels of cultivable land per person, but is reduced by intensification of agriculture. An improved agricultural policy environment is likely to stimulate the destruction of wilderness area by farmers. In addition, it is hypothesized that better educated people will show more concern about the environment and, hence, that countries with higher rates of primary school enrollment will have lower rates of wilderness loss.

28. The statistical regression analysis uses the percentage of wilderness loss since 1900 as the dependent variable. The result is as follows:

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	76.9	8.8	1%
Cultivated ha per person (a)	-7.2 (b)	1.4	17%
Fertilizer use per ha (a)	-2.6 (b)	1.1	28%
Primary school enrollment rate	-0.2	1.9	7%
Agricultural policy dummy	11.0	1.8	8%

Adjusted R squared = 0.15

F statistic = 2.5

(a) Converted to natural logarithm.

(b) Represents elasticity.

29. The coefficients are consistent with the hypothesis, although cultivated hectares per person and fertilizer use per ha are not significant at the 90 percent level. The results are interesting enough to suggest the plausibility of the hypothesis, especially in conjunction with the site-specific evidence presented in the text. Further statistical testing is now underway.

30. The coefficients suggest the possibility that the greater the available area under cultivation per person, the lower the rate of wilderness loss. The higher the intensity of fertilizer use, the less the wilderness loss. The greater the percentage of school-age children in primary school, the lower the wilderness loss. Good agricultural policy is associated with high rates of wilderness loss -- presumably because policy conducive to agricultural production growth stimulates acreage expansion when other means to increase farm output (e.g., modern inputs, sustainable intensification technologies) are unavailable. However, the overall equation explains only a small part of the variation among countries in the loss of wilderness areas. Factors such as land tenure, expanse of parks and reserves and government efficiency in managing these, and development of infrastructure in wilderness areas are likely to affect the maintenance of wilderness area. Data problems also explain some of the lack of fit.

31. If further testing establishes the statistical validity of these results, the operational conclusion will be that a reduction in the rate of population growth, intensification of agriculture, and expanded primary school education would reduce the speed of wilderness loss. Since it would not be legitimate to distort agricultural policy significantly in order to conserve the wilderness, the negative impact on the wilderness of favorable agricultural policy will have to be offset. This again underscores the importance of environmental action plans and land use planning. Unfortunately, the statistical

analysis tells nothing of the need for land tenure reform, the desirability of expanding protected areas, and other actions to conserve the wilderness.

E. Variations in Total Population Fertility Rates Among Countries

32. Total fertility rates (TFRs) in Sub-Saharan Africa, shown in Table 2, are hypothesized to be related to the independent variables as follows: positively to infant mortality (the higher the expected loss of infants, the more births are desired in order to assure that there are some survivors); negatively to food security (the greater the food security, the lower the need for children to provide family labor for food production since other factors of production are available to substitute for child labor); negatively to female primary school enrollment (better educated women want smaller families); positively to cultivable land per person (the more cultivated land per person, the greater the need for family labor to help cultivate it since there are few other available factors of production and since open-access land tenure allows more land for households with more labor); and positively to the rate of deforestation (the higher the rate of deforestation, the greater the need for child labor to help with wood gathering and water fetching).

33. These hypotheses are tested by means of a statistical regression in which the TFR is the dependent variable. The result is as follows:

<u>Independent Variable</u>	<u>Coefficient</u>	<u>T-statistic</u>	<u>2-Tail Significance Test</u>
Constant	6.5	4.2	1%
Female primary school enrollment rate	-0.005	0.9	37%
Cultivated ha per person (a)	0.16 (b)	0.6	53%
Infant mortality rate	0.01	2.0	6%
Calorie supply as % of requirement	-0.02	1.2	25%
Deforestation rate	0.29	2.4	2%

Adjusted R squared = 0.4

F statistic = 5.5

(a) Converted to natural logarithm.

(b) Represents elasticity.

34. The coefficients are consistent with the hypothesis, but only infant mortality, the rate of deforestation, and the constant term are statistically significant at the 90 percent level or better (i.e., with a two-tailed significance test of 10 percent or lower). The relatively poor fit of the equation and some of the variables may be explained by the poor data, as well as the fact that there is considerably more behind the explanation of TFRs than is explained here, such as age at first marriage for women, cultural links between female fecundity and social status, and so forth. As a result, an expanded data set is being developed to test the hypothesis using pooled cross country and time series data.

35. The statistical result, when combined with the site-specific evidence referenced in the test suggest that the higher the percentage of female primary school enrollment, the lower the TFR, although the coefficient is not statistically significant. The greater the area cultivated per person, the higher the TFR (although again the coefficient is not statistically significant). The higher the infant

mortality rate, the higher the TFR. The better the level of nutrition, the lower the TFR.³ Better nutrition not only translates into better maternal and child health (and, hence, into lower infant and child mortality), but also reflects the ability to feed oneself and one's dependents with the available factors of production, including household labor, and this in turn lowers demand for child labor (one hypothesis of this study). The positive and significant correlation between better nutrition and lower TFRs may also reflect the beginnings of the demographic transition -- as better-off people (having access to more food) reduce their family size.

36. The highly significant positive association between the rate of deforestation and the TFR is noteworthy: the higher the rate of deforestation, the higher the fertility rate. This may reflect, as hypothesized, the greater demand for child labor as environments deteriorate (greater distances to walk to obtain fuelwood and water and more labor required to produce sufficient food as the productivity of farm land deteriorates due to deforestation). Unfortunately, this type of analysis cannot establish causality, and causality may in fact be running in the opposite direction -- i.e., higher fertility leading to faster population growth and more rapid deforestation.

³ This applies when holding infant mortality constant (better nutrition reduces infant mortality); the relationship here works independently.

Data Used For The Statistical Analyses

The data used in this statistical analysis are reproduced in the tables on the following pages. Each variable is identified with a code, given below, along with a definition of the variable and the source of the data used. The data in the statistical tables at the end of the book are the most recent available, in May 1992. The data used in the statistical analysis pre-dated this.

- POPG** Population growth rate, annual average 1965-1990: World Bank (1991c) and the 1991 revision of World Bank demographic estimates and projections.
- INFM** Infant mortality per 1000 live births, 1965-1990 average: World Bank (1991c).
- PRISC** Primary school enrollment, % of age group, average 1965-1987: World Bank (1991c).
- TOTFR** Total fertility rate 1985-1989: World Bank (1991c) and the 1991 revision of World Bank demographic estimates and projections.
- FDSEC** Average daily calorie intake per capita, 1988: World Bank (1991c).
- CAL%** Average daily calorie supply per capita as percentage of minimum requirement, 1988.
- POL** Agricultural policy appropriateness 1980-1987 (dummy variable); based on judgement by World Bank staff (1 = appropriate policy, 0 = inappropriate policy).
- DEFORS** Average annual rate of deforestation in the 1980s: World Bank (1989d).
- WILDLS** Total Percentage wilderness destruction, 1900 to present: WRI/IIED (1988).
- FERT** Fertilizer use per ha (100 g/ha), 1987/89: World Bank (1991c).
- PRIF** Primary school enrollment of females, average 1965-1988, % of age group: World Bank (1991c).
- CERY** Cereal yields, kg/ha, 1984-1986: FAO Production Series.
- MZ** Maize yields, hundred kg/ha, 1989; source: FAO Production Series.
- RIC** Rice yields, hundred kg/ha, 1989; source: FAO Production Series.
- SOR** Sorghum yields, hundred kg/ha, 1989; source: FAO Production Series.
- CAS** Cassava yields, hundred kg/ha, 1989; source: FAO Production Series.
- PCLD65** Per capita arable land actually cultivated, 1965 (ha/person): Table 17.
- PCLD87** Per capita arable land actually cultivated, 1987 (ha/person): Table 17.
- PCLDA** Average per capita arable land actually cultivated, 1965-1987 (ha/person): Table 17.

Statistical Appendix

<u>Table No.</u>	<u>Page</u>
1. Sub-Saharan Africa: basic indicators	148
2. Sub-Saharan Africa: population growth and fertility rates	149
3. Sub-Saharan Africa: crude birth and death rates, infant and child mortality rates, 1965 and 1990	150
4. Population estimates and projections based on targeted decline of 50 percent in total fertility rate by 2030	151
5. Sub-Saharan Africa: required contraceptive prevalence rates for achieving population projections in Table 4	152
6. Demand for contraception and its components among currently married women	153
7. Developing countries by strength of family planning programs, 1989	154
8. Total fertility rates, desired number of children, infant and child mortality rates, and contraceptive prevalence rates	155
9. Sub-Saharan Africa: performance of the agricultural sector	156
10. Sub-Saharan Africa: food security	157
11. Sub-Saharan Africa: crop yields	158
12. Sub-Saharan Africa: growth rates of cereal and major export crop yields	159
13. Sub-Saharan Africa: agricultural exports - value and volume	160
14. Sub-Saharan Africa: producer price shares	161
15. Sub-Saharan Africa: irrigation and fertilizer use	162
16. Sub-Saharan Africa: land use	163
17. Sub-Saharan Africa: per capita arable land	164
18. Sub-Saharan Africa: forest area and deforestation	165
19. Sub-Saharan Africa: fuelwood supply and demand	166
20. Sub-Saharan Africa: wildlife habitat loss in Afrotropical nations, 1986	167
21. Sub-Saharan Africa: droughts	168
22. Soil erosion in selected countries of Sub-Saharan Africa, 1970-86	169
23. Extent of soil degradation in major regions of the world, early 1980s	170
24. Results of financial and economic analyses of various land resource management technologies	171

Projections are based on present trends. Hence the slight decline in growth rate results only from the slightly declining trend in a few countries. The projections include the position impact of HIV. They do not include the impact of more successful population programs.

Total fertility rate (TFR) is the average number of children who would be born alive to a woman (or group of women) during her lifetime if she were to pass through her childbearing years conforming to the age-specific fertility rates of a given year.

Table 3: crude birth and death rates, infant and child mortality rates, 1965 and 1990

Country	Crude birth rate per 1,000 population		Crude death rate per 1,000 population		Infant mortality per 1,000 live births		Child mortality (under age 5) per 1,000 live births

.. indicates less than 500,000.

a. Projection assumes that a 50 percent decline in the total fertility rate from the 1985 level will be attained during 2025-30. These projections assume that the pace of decline in the future will be significantly higher than has hitherto been observed.

b. Excluding South Africa.

c. Even when the Net Reproduction Rate (NRR) reaches one, the age structure is such that the number of women in, or yet to enter, their childbearing years gives rise to total births exceeding the total number of deaths. The population, therefore, will increase for a further considerable period before reaching its hypothetical stationary level. All countries are projected to reach stationary population near the end of the 22d century.

China	81.2	85.0	82.6	82.8

a. The estimated contraceptive prevalence rates (CPR) were derived by applying Bongaarts' model to available country-specific information including data on CPR, contraceptive mix, and proportion married, with assumptions on likely changes. (For countries without such information, proxy data from countries with a similar socio-cultural background were utilized.) The CPR estimates refer to the percentage of women aged 14-49 using contraception (both modern and traditional). For India and China, they refer to married women aged 15-44. Countries in the above table are selected on the basis of the size of population (over 5 million) and/or availability of Demographic and Health Surveys information, Phase I (Oct. 1984-Sept. 1989).

Note: All figures except the last column with selected countries are percent of currently married women. Total demand includes method failures, current use, and unmet need. Unmet needs include non-use among women who would like to regulate their fertility. Percent of demand satisfied is the proportion of current use to total demand.

g/ Average per capita daily calorie supply data for 1986-1989 divided by requirement established by the WHO for each country.

Note: Food security is defined as access to enough food for an active and healthy life. The minimum daily calorie requirement to meet the energy needs of an average healthy person, as calculated by the World Health Organization of each country, is taken into account. Index of food production, cereal imports, per capita calories supply 1965: World Development Indicators 1992, except for Guinea-Bissau, The Gambia, Comoros, Sao Tome and Principe, Cape Verde, Seychelles, Swaziland for which the source is the World Bank. Sub-Saharan Africa: Crisis to Sustainable Growth, 1989. Per capita calorie supply 1986-1989: African Development Indicators, 1992; World Bank/UNDP p. 322.

Note: Habitat is a place or type of site where a plant or animal naturally or normally lives and grows. The Afrotropical realm is defined as all of the continent south of the Sahara Desert, including the island of Madagascar. Therefore, data for Mauritania, Mali, Niger, Chad, and Sudan cover only parts of these countries. Comoros, Seychelles, Sao Tome and Principe, Mauritius, Rodrigues, Reunion, and the extreme southeastern corner of Egypt are not included.

Indigenous rock bunds	Sheet erosion; incipient gulying	25	2	1	24.2	1.17	66.6	1.84	64.8	2.09	165.2	3.04	57

a. Yield increment benefits were based on the following:

Vetiver grass contour hedges Fanya juu contour bunds Stone-faced terracing	Wiggins (1981) in an analysis of similar slopes and rainfall conditions in El Salvador allowed for a 1% yield increment to account for retention of fertilizer and seeds once project is in place; a somewhat higher figure was judged appropriate for southeastern Nigeria.
Improved acioa system	No yield increment is assumed as the improved system is meant to produce an extra crop one year in four
Alley cropping	IITA studies over the years have demonstrated yield improvements for maize in excess of 40% under alley cropping (Ngambeki and Wilson, 1984; Ngambeki, 1985). For cassava under southeastern Nigerian conditions, Kang et al (1989) report yields of 15 to 20 t/ha on alley farmed areas compared to 14 t/ha on traditional plots with no fertilizer. Alley farm yields vary according to whether prunings are or are not applied with or without fertilizer, and depending on the tree species planted in the hedgerows. Because of the early stage of research, a conservative 20% yield gain was assumed.
Animal traction	There is considerable debate concerning yield gains under animal traction. Pingali et al. (1987) review a large number of studies and conclude the yield impact is minimal, especially when observing an individual farmer converting to animal traction from the hoe without an improvement in the quality of tillage. As a result, only a minimal yield improvement of 5% was assumed here.
Fodder bank	ILCA researchers have demonstrated large yield gains for maize planted in rotation with stylo-based fodder banks. Mohamed Saleem et al (1985) report a doubling of yields on fodder banks compared to yields on lands fallowed for many years. Tarawali et al. (1987) report an 85% increase for test plots in the sub-humid zone. A conservative figure of 40% was assumed here.
Grazing reserve	Bincan (1988) assumes that a program of grazing reserve improvements could raise carrying capacity from one TLU per 8 ha to one per 6 ha, for an increase of 33%; this assumption is adopted here.
Tree shelterbelt Fanya juu contour bunds Stone-faced terracing	Yield increments are taken from Anderson (1987), who extensively reviews the literature on shelterbelt effects. Since vetiver hedges have not been studied greatly, a conservative figure of 10% was adopted.
Indigenous rock bunds	OXFAM's project in Burkina Faso demonstrated yield gains from 9% to 40%, depending on rainfall conditions (Younger and Bonkoungou, 1989). For Nigeria, a figure of 25% was assumed, but rainfall conditions will be important in determining ultimate yield benefits.

b. Annual yield decline figures were derived as follows:

Vetiver grass contour hedges Fanya juu contour bunds Stone-faced terracing	Using soil loss-yield relationships developed by Lal (1987) for a 15% slope in southern Nigeria, yield loss per year would be 3.5% (assuming a beta value of 0.04 to account for cassava being relatively tolerant of soil loss), on a 5% slope (to imitate project conditions), yield loss per year would be approximately 1%.
Alley cropping	Higging and Antoine (in preparation) report maize and yam yield reductions of about 50% over 15 years and 6 years, respectively, in southern Nigeria on continuously cropped fields. Cassava's yield decline is slower than yam, with 5% selected as an arbitrary figure.
Animal traction	Based on Higging and Antoine (maize yield decline), but since some fallowing is assumed to exist, the yield decline without the improvement is taken as somewhat lower. Manuring and better ridging is assumed to reduce annual yield decline by one half under animal traction, while yield decline is assumed to be fully arrested with fodder banks.
Grazing reserve	An arbitrary decline of 2% per year under existing conditions is assumed.
Tree shelterbelt Fanya juu contour bunds Stone-faced terracing	Annual decline without improvement is taken from Anderson (1987), but an allowance of some continued decline (1% per year) is made here, although not by Anderson.
Indigenous rock bunds	Figures used are arbitrary and are meant to take account of declining fertility due to shortened fallows and to wind erosion, as well as sheet erosion effects.

c. Assumes average yields, cropping intensity and yield declines as indicated.

d. Assumes yields at 75% of average, cropping intensity doubled and yield decline at 50% of above indicated value (except wave bedding, where no yield loss is considered, and alley cropping, where intensity is already 100%).

e. Measured as the value of the potential food imports displaced by yield benefits plus fuelwood benefits/total benefits.
